So late an authority as Landois and Stirling authorize this view. J. B. Murphy logically attacks this question, and as a result of experimental and practical study asserts that it has nearly the same function as the second bulb of a syringe in regulating the flow of bile, causing a steady stream rather than an intermittent current into the duodenum. Cholelithiasis is the most common pathological condition of the gall bladder for the relief of which surgery offers the only rational method. It is gratifying to us as Americans to see the important part played by our countrymen in this work, and to note that to Dr. Bobbs of Indianapolis, is due the credit of priority of performance of the modern operation in 1867. Gall stones, as a rule, are formed in the gall bladder itself as a result of precipitation and accretion. Under some circumstances stones are also found in the hepatic ducts, especially in cancerous obstruction. The diagnosis depends largely upon the history, character and location of the pain,

and often physical examination will reveal a tumor in this region. Jaundice does not appear unless the common duct is obstructed and is far more common in malignant disease, and for the same reason the color of the stool, upon which much stress has been laid, is usually of small importance. The diagnostic value of the finding of gall stones passed with the stool is absolute, but I am inclined to think that such passage of gall stones is less common than generally thought, and certainly the onset, duration and cessation of a colic is no indication that a stone has been passed, but merely that the cystic duct has been obstructed and that either the obstruction has been removed or the bladder has exhausted itself in the effort. When olive oil in large quantities was a popular remedy for hepatic colic, the soap balls passed with the stool, and resulting from the action of the intestinal alkalies upon the oil were erroneously supposed to be the offending bodies, and as such exhibited to the sufferer and his admiring friends. At the present time we hear much less about stones found in the feces. While stones may be passed through the ducts, or by ulceration, into the intestine, externally, or into any neighboring viscous, or after causing years of suffering remain quiescent without producing further trouble, such fortunate outcome is very exceptional, and in the majority of instances operation is the only relief from a life of suffering or death from a complication. Septic infection of the gall bladder, either as a result of stones, or from extension upward through the ducts of a septic process is a not uncommon occurrence, and may result either in chronic inflammation or empyema. Fenger has done much to elucidate this subject.

Large accumulations in the gall bladder are not infrequently confounded with right renal tumors or even with ovarian cysts, and many such mistakes are recorded, especially when dropsy of the gall bladder exists with great retention of catarrhal products as a result of duct obstruction. Injuries of the gall bladder sometimes occur. Some years ago in the practice of my father I saw a case of undoubted rupture of the gall bladder. A boy 12 years of age was thrown from a wagon, the wheel passing partly on to the right side of the abdomen. Acute developed and large quantities of thin bile were aspirated at different times during a month. Complete recovery took place. Operations upon the gall bladder may be divided into three general classes:

First, cholecystostomy, or the simple opening and removal of stones. Following that master of abdominal surgery, Lawson Tait, this operation is usually done at one sitting and the open gall bladder stitched into the incision, forming a temporary fistula. As bile is not septic and does not cause peritonitis, other than the adhesive variety, slight biliary contamination of the peritoneum causes no harm, and this open method enables us to manipulate with the finger inside the abdomen, outside of the gall bladder, which at times is a great aid in extracting stones. It also allows the subsequent escape of overlooked stones. If the contents of the gall bladder be septic upon aspiration after the abdominal incision is made, it is far safer to stitch it into the incision and delay opening for several days until adhesive inflammation has shut it off from the general cavity.

Blind aspiration of the gall bladder has long been known to be of great danger; not, as supposed, on account of the escape of a few drops of bile, but

REPORT OF SEVEN OPERATIONS UPON THE GALL BLADDER OR ITS DUCTS.

Number, Initials, Residence.	Nat. Age, Sex.	Location, Office.	Date and Place of Operations.	History.	Examination.	Operation.	Result.	Remarks.
1. L. R. H., Steep Eye, Minn.	Am. 36, M.	Hospital Staff.	Dec. 2, 1890, St. Mary's Hospital, Rochester.	Colic for several years; during last year continuous pain in right side, has had some morphia constantly.	Emaciated, yellow. Tumor in right hypogastrum.	Incision over tumor, single stone, gall bladder adherent.	R. Fistula closed in three weeks.	
2. F. L., St. Charles, Minn.	Ger. 43, F.	Dr. Chamberlin, St. Charles, Minn.	June 24, 1891, St. Mary's Hospital.	Colic began nine days after childbirth, two years ago. Constant pain and frequent colics.	Indefinite tumor, great tenderness in right hypogastrum.	Incision in right semi-lunaris. One large stone impacted in cystic duct.	R. Great difficulty was experienced in dislodging stone. Fistula healed in two weeks.	
3. G. Z., Dover, Minn.	Ger. 28, F.	Dr. Dugan, Dover, Minn.	Feb. 3, 1892, St. Mary's Hospital.	Attacks of pain, with more or less jaundice during last year. Pain in pelvis.	Liver very large. Small tumor in pelvis.	Incision in R. S. No stone. Common duct blocked by adhesions which were torn loose. Incision in median line. Papillary cyst of ovary removed.	R. Patient improved greatly for six months. In nine months died from malignant papilloma of peritoneum.	
4. E. J. D., Quincy Mills, Minn.	Am. 35, F.	Dr. Chamberlin, St. Charles, Minn.	Aug. 17, 1892, Home.	Repeated colic for attacks of peritonitis.	Patient jaundiced with symptoms of acute obstruction.	Gall bladder very adherent. Peritonitis. Ninety-six stones.	R. Patient died in a few hours. Operation lasted but twenty-five minutes.	
5. S. A. H., Plainview, Minn.	Am. 37, F.	Dr. Walste, Plainview, Minn.	August 29, 1892, St. Mary's Hospital.	Colic for seventeen years. Constant pain in right side.	Pain and tenderness in right hypogastrum. No tumor.	Incision in R. semi-lunaris. Gall bladder adherent. Fifty-six stones sutured to skin.	R. Fistula healed in four weeks.	
6. C. S., Portland, Minn.	Ger. 56, F.	Dr. Adams, Elgin, Minn.	Dec. 6, 1892, St. Mary's Hospital.	Pain for six months. Tumor forming in right side two months.	Movable tumor in right hypogastrum. Empyema gall bladder.	Incision over tumor. Murphy evacuated. Sutured and drained.	R. Fistula healed in three weeks.	
7. W. H., Racine, Minn.	Am. 71, M.	Dr. Plummer, Hamilton, Minn.	April 6, 1893, St. Mary's Hospital.	Colic for two years. Jaundice for two months.	Great debility, cholera, white stools, etc.	Incision R. S. Bladder deep. No stone. Obstruction in common duct. Anastomosis by Murphy's button.	R. The bladder could not be brought to surface. Obstruction could not be removed. The Murphy button worked quickly, and relieved jaundice, etc.	

because of the contents being often septic and the slight leakage setting up septic peritonitis.

Suture of the gall bladder after opening and removal of stones is seldom practiced and the method is condemned as unsafe. This, however, is not logical—the whole question of safety depends on the patency of the ducts. If there be no obstruction to the outflow, so that there will be no tension within the sac, suture and return is a safe procedure. Abbe tests the condition of the ducts by using a syringe and forcing water through them into the intestine; if the fluid passes freely he does not hesitate to trust to immediate suture and return.

The second general class is where the gall bladder is removed. Langenbeck first practiced cholecystectomy and formulated indications for its performance; he gives much too wide a scope to this procedure, and Greig Smith very properly limits its application to single or double stone, where the fundus of the gall bladder can not be sutured to the abdominal wall, or to cases wherein the tissues are too thin or inflamed to bear a suture. It is mainly practiced by a few continental surgeons and is not a popular operation.

The third class is a very important and often perplexing one—wherein obstruction exists either in the cystic or common duct. To suture such a gall bladder to the abdominal walls is to invite a permanent fistula; in any case an annoyance, and if complete obstruction of the common duct exists the escape of all the bile externally leads to debility and eventually death. Fortunately, the recent work of Mr. J. Knowlesley Thornton, Mr. Mayo Robinson, Robert Abbe, and Charles McBurney has given us methods of opening these ducts and removing stones with either suture of the incised duct or drainage. The

latter distinguished surgeon has successfully opened the duodenum and shelled an impacted stone out of the intestinal orifice of the common duct. There will remain certain cases in which the obstruction in the ducts can not be removed, and in these cases entero-cholecystotomy is our only hope of success. Winniwater first sutured the gall bladder to the colon; while this was much better than an external fistula, yet most of the physiological effect of the bile in digestion was lost. Gaston of Georgia, by experiments upon dogs developed a complicated method of suture to the duodenum; but it remained for a brilliant young Western surgeon, J. B. Murphy, to invent his mechanical device by means of which an effectual back door for the escape of bile into the duodenum can be safely and quickly made. In conclusion, I append a diagrammatic report of seven cases in which I have operated upon the gall bladder or its ducts.

SPECIMENS DEMONSTRATING THE OPERATION OF GASTRO-CHOLECYSTOTOMY, END-TO-END ANASTOMOSIS OF GUT, AND THE CONNECTING OF THE GALL BLADDER WITH THE ALIMENTARY TRACT.

AS PERFORMED WITH THE MURPHY BUTTON, AND BY THE MAUSSELL OPERATION.

Read before the Section on Surgery and Anatomy at the Forty-fourth Annual Meeting of the American Medical Association.

BY B. MERRILL RICKETTS, M.D.
(CINCINNATI, O.)

I am sorry, indeed, that circumstances would not permit of my being with you this morning as an-

nounced on the program. However, I must content myself with the time allotted to me this afternoon, a duly appreciated courtesy granted by the chairman, Dr. Murphy having demonstrated his gall bladder operation upon the dog prevents me from making anything more than a passing remark upon this operation. However, I wish to speak more fully upon the various other anastomoses.

No. 1.

That I might simplify matters both in my remarks and demonstrations I have, with the assistance of an artist been able to give charts that are more instructive than words.

No. 2.

Six of these fully illustrate an end-to-end anastomosis, while four show the operation upon the stomach as suggested by Maunsell of New Zealand, some eleven years ago, but which was not published and made known until one year ago.

No. 3.

No. 4.

Although I have operated frequently upon the dog in this manner, I know of no person except Dr. Frank Hartley of New York, who has made the operation upon the human being. This Dr. Hartley did in the month of May, 1892, for carcinoma of the gut.

No. 5.

He informed me last November while I was in New York that the patient (a man) was living and doing well at that time. I suppose that we will hear from Dr. Hartley concerning this case.

No. 6.

This operation, when understood, can be made by the average practitioner without much preparation; all that is needed being a knife, scissors, needle and thread.

Fig. A.

With this, as with all other devices for anastomosis, greater difficulty is experienced in gut of small caliber, and I find less difficulty in making connec-

tions with the dog's gut as it approaches the caliber of the average human alimentary tract.

Fig. B.

My work with the Murphy button has been very satisfactory indeed, but the Murphy button is not and will not be found in the possession of 10 per cent. of the practitioners. Then, too, there is noth-

Fig. C.

ing left within the alimentary tract to jeopardize the life of the patient in its passage through that tract. Having not seen Mr. Mammell's description of the

operation, and having depended upon a short statement and one illustration, I have been left to learn of the operation through personal experimentation. I have thoroughly satisfied myself by this means, together with the statements by Dr. Hartley, that his operation was a success, and I am now ready to recommend it as one of the best means we have for the various anastomoses within the abdominal cavity.

No. 1 represents ends to be united.

No. 2 represents the ends of the fixation sutures, which have been drawn through the opening made in the gut for the purpose of invagination. These are the sutures that are removed after invagination has been produced, because the knots are on the peritoneal surface.

No. 3 represents the sutured ends drawn through the opening, and fixation sutures just before removal.

No. 4 represents completion of suturing, all the knots of which are on mucous side.

No. 5 shows partial reduction of invagination and stage of operation when ends of sutures are cut.

No. 6 shows appearance of gut after reduction and suturing the opening purposely made for invagination, also that the knots of sutures are within.

Fig. D.

Connection with the stomach is accomplished by making two incisions in that organ, as shown in Figs. *a*, *b*, *c* and *d*. The object is to insert the smaller into the larger one.

I am sorry that my remarks are so limited, but I feel that, together with the diagrams, enough has been said to fully illustrate the operation.

Medical Detectivism.—Dr. Conan Doyle's tales of detective acumen has made famous one of his medical teachers in the University of Edinburgh. The latest paragraph about Dr. Bell is the following:

"Professor Joseph Bell of Edinburgh is the original of Sherlock Holmes. Some years ago Professor Bell was medical examiner for an insurance company and an Edinburgh man presented himself for examination. After the victim had stripped to the waist, the professor poked him in the ribs and said:—"You have belonged to the Volunteers?" The gentleman admitted that was the fact, but said his volunteering had been done years before. It seems that certain muscles are developed by a military life, and that the professor knowing the man was not a soldier, and seeing those muscles developed on his body, at once jumped to the correct conclusion that he had been a Volunteer."

THE ESTABLISHMENT AND MAINTENANCE OF AN ARTIFICIAL URETHRA ABOVE THE SYMPHYSIS PUBIS IN CHRONIC PROSTATIC OBSTRUCTION.

Read in the Section of Surgery and Anatomy, at the Forty-fourth Annual Meeting of the American Medical Association.

BY D. J. HAYES, M.D.

MILWAUKEE.

Professor of Surgery of the Genito-urinary System in the Post-Graduate School of Medicine, Chicago, Ill.

I propose to call your attention to an operation for the relief of an extremely distressing and painful form of disease in men, the relief of which was very inadequate until of very recent date. I refer to the establishment of a urethra above the pubic bone in chronic prostatic obstruction.

From a series of over two hundred post-mortems prosecuted by Sir Henry Thompson on male patients over 55 years of age, to determine the percentage of those who were affected with prostatic enlargement it was found that about one in three had more or less enlargement, and only about one in seven of those exhibited symptoms of the disease during life. Consequently we may expect about one man in twenty who is approaching 60 years of age to consult us for this difficulty.

As a rule, enlargement of the prostate takes place in all directions, with occasionally the development within it of separate tumors resembling uterine fibromyomata. Sometimes only one lobe is affected, and again the whole trouble may be due to overgrowth of the middle lobe, which when enlarged gives rise to complete retention.

As the gland enlarges, the length of the prostatic urethra increases, often reaching four inches in length. The vesical orifice is thrown up behind the symphysis, and the curve of the prostatic urethra is much increased, which explains the difficulty often experienced in introducing an instrument into the bladder, and has led to the use of specially devised instruments to traverse the deformed urethra.

In advanced prostatic obstruction the greater portion of the bladder is lower than the internal orifice of the urethra, and forms a pouch behind the prostate. More or less residual urine is left in this pouch after each act of micturition. The obstruction as well as the residual urine increases from month to month and from year to year, and undergoes ammoniacal fermentation from the presence and action of putrefactive bacteria, producing irritation and progressive infection. Inflammation extends from the mucous to the submucous and muscular coat. The bladder walls become hypertrophied from overwork. Contraction takes place with loss of extensibility.

The urine which is loaded with mucus, pus and putrefactive bacteria, is forced back into the ureters, distending and producing inflammation in them.

On account of the stagnation of putrid urine in the bladder and ureters, more or less of this urine is left in the pelvis of kidneys, ending in pyelo-nephrosis or surgical kidney, from which the patient dies, but not until after months and perhaps years of the most intense suffering.

Many cases of cystitis due to prostatic obstruction are entirely relieved by rest and attention to the general health, while in more advanced prostatic disease the distressing symptoms may be relieved by withdrawal of the residual urine with the catheter and

thoroughly irrigating the bladder with antiseptic solutions and proper internal treatment. In another class of cases of which I wish to speak more fully the obstruction is more or less complete. Perhaps not a drop of urine can be passed without the use of the catheter. The bladder is much contracted and the use of the catheter becomes a necessity from fifteen to twenty times a day. The increased growth of the prostate makes the canal difficult to traverse, alike for the surgeon and patient. He only experiences half an hour's rest at night when a desire comes to urinate; again another attempt is made to pass the catheter through the deformed urethra. His powers are taxed to the utmost for continuous sleep is out of the question and his health rapidly declines. Among some of the many operations which have been devised from time for the reduction of prostatic hypertrophy may be mentioned, first, the injection into the prostate with a curved needle of a solution of iodine and iodid of potassium (Heine) which not only gave negative results, but proved to be dangerous. Many competent observers have spent both time and money with electricity without showing any brilliant results. The different methods of compression which have been used have not been attended with success, notwithstanding their frequent and continued recommendation. Internal medical treatment has been as ineffectual as compression.

Mercier's method of punching out a portion of the middle lobe through the urethra by a specially devised instrument has had few advocates and was never used to any extent on this side of the Atlantic.

Another operation which is more recent, and with which the name of Reginald Harrison is intimately connected, consists in opening the bladder by a median perineal incision, dividing the obstructing portion of the prostate and retaining a tube in the opening for six or seven weeks; large bougies are subsequently passed to keep the wound open, when finally it is allowed to heal. The low operation has many disadvantages. First, the patient who is generally in a poor condition of health from long suffering is confined to bed for many weeks; secondly, when the tube is withdrawn and the patient is up and around, there is a constant dribbling of urine, and when the opening is allowed to heal, all the old symptoms are liable to recur.

Prostatectomy, supra pubically through the perineum, or combined, has given brilliant results in many cases in the hands of McGill, Guyon, Moullin, Belfield, Keyes and other enthusiastic workers in the department of surgery. As a rule, patients who submit to this operation are men well advanced in life, and worn out by long continued suffering have renal complications, and the mortality must necessarily be high from uremia and sepsis. The question now arises, can anything be done by any other operative measures for the permanent relief of those cases? It can be answered in the affirmative. By the establishment and maintenance of a urethra above the symphysis pubis. The honor of having first planned and performed this operation belongs to Dr. Hunter McGuire. The technique of the operation is about the same as supra pubic cystotomy for vesical calculus. The patient is prepared the same as for any other abdominal operation. The rectal bag is introduced and distended with fluid. The bladder is thoroughly cleansed with a one-sixth per cent. solution of salicylic acid, which has the advantage over other solutions

of removing completely all the mucus and pus from the bladder wall, which is an important point in the subsequent steps of the operation.

The bladder is distended with the same fluid. The supra pubic region is thoroughly disinfected. The incision is made down to the bladder in the usual way and the bladder is opened on a line with the upper border of the pubic bone. The rectal and bladder distension raises the bladder in the pelvis, consequently the peritoneum is not encountered.

After the bladder is opened the interior is thoroughly explored for vesical calculus, tumors, etc. If there is obstruction at the outlet of the bladder due to projection of the middle lobe, its removal should be attempted if the patient's strength will admit. Any of the tissues should not be lacerated during the operation; particularly is this true of the loose cellular tissue surrounding the bladder as it opens avenues for subsequent urinary infiltration. The bladder walls are not sewed in the wound but allowed to drop back into the pelvis. A large gum catheter is introduced through the wound into the bladder and the urine removed by siphon action. When the wound contracts down to the size of a ten or twelve English catheter the opening is maintained by wearing a plug which resembles a tracheotomy tube, at least a portion of the time. When the desire comes to urinate the plug is removed and the bladder empties itself through the artificial urethra with considerable force. The urethra which is now established is from three-fourths to one and one-half inches in length. In the intervals of micturition the recti muscles and other tissues close the opening and there is no dribbling of urine whatever.

Within the past year I have established an artificial urethra above the symphysis pubis in two cases; both were very great sufferers and in both the time had arrived when the introduction of the catheter was difficult both for the patient and surgeon. One of them has kindly consented to appear at the meeting this afternoon. He is a man nearly seventy-two years of age, and has always enjoyed excellent health until about five or six years ago, when his trouble first commenced with frequency of urination, particularly at night. He grew progressively worse, and for the past six months previous to the operation he was not able to leave the house and was introducing the catheter from fifteen to twenty times a day. He was suffering fearfully, notwithstanding the use of large doses of morphine. His urine contained large quantities of mucus pus and bladder epithelium. Although he had been a very great sufferer for some time no evidence of renal disease could be found by either chemical or microscopical examination of the urine, which is exceptional in a case that has had disease in the lower portion of the urinary tract so long. He was very anemic and his health was rapidly declining. He consented to an operation which was performed on April 11, 1893. The preparatory treatment consisted in irrigating the bladder twice daily for three or four days previous to the operation with a saturated solution of boric acid containing one-sixth per cent. of salicylic acid, trit. repens, and salol internally. The bladder was opened in the usual way and in a pocket behind the enormously projecting prostate were found a few small stones which were removed. The bladder was allowed to drop back in the pelvis and a large drain introduced through the wound into the bladder. No

attempt was made to remove any of the projecting portion of the prostate as the patient's enfeebled condition would not admit of it.

There was some temperature following the operation. The bladder was irrigated three times daily through the tube and dilated as much as possible by hydraulic pressure. He was relieved from pain immediately after the operation and has taken no morphine since. His urine is now clear from mucus and pus and he is able to hold his water from three to five hours during the day and only arises once or twice at night. When the wound contracted down to the size of a number 10 English catheter the plug which resembles, as you will observe, a tracheotomy tube, is introduced for at least a portion of the day to maintain the opening. The patient is now able to empty the bladder completely through the artificial urethra which is just one inch in length. The urine is often expelled several feet from the body. There has been no dribbling of urine whatever since he is up and about. He has gained very rapidly since the operation and you will observe that he is in good condition. He eats well and sleeps well and goes to his place of business daily. He is an enthusiastic advocate of the operation and those who wish to examine him may do so.

The next case was a man 64 years of age. He had been suffering more or less for six years; for some months previous to the operation he was passing a catheter from twelve to fifteen times a day. He had a severe cystitis and his bladder was contracted; rectal examination with a sound in the bladder showed the prostate greatly enlarged in both longitudinal and transverse diameters. His urine was loaded with mucus, pus, and occasionally contained small quantities of blood. He had been treated for some time with antiseptic irrigations of bladder and morphine suppositories. The operation was made in the usual way; the bladder walls were found greatly thickened and sacculated.

In the course of two weeks he was up and about, and when the wound contracted down to a number 10 English catheter, which was about six weeks, the plug was introduced to maintain the opening, and worn a portion of the time. There was some necrosis of the prevesical tissues due to contact with the septic urine. To obviate this danger Dr. W. T. Belfield, of Chicago, recommends making the operation in two stages; at the first operation merely exposing the bladder and packing the wound with gauze until granulations are established, five to seven days, then opening the bladder and completing the operation. The urine is now free from mucus and pus, and he is able to hold it from three to five hours at a time. Both patients are enthusiastic advocates of the operation.

The question might be asked: Is this simply a palliative or ultimately a curative operation? The limited time that has elapsed since my operations will not admit of my answering this question from my own personal knowledge. Dr. McGuire who has had a large experience with the operation reports gradual reduction of the size of the prostate with final restoration of the powers of micturition by the natural route. This is not unreasonable to expect when we consider the greater portion of the hyperplasia is due to the disturbance of urination which constantly exists. And when the bladder and prostatic are put at rest gradual absorption of the ob-

structing tissues might take place. No case in the whole field of surgery can appeal more to our sympathies than a man with advanced cystitis due to prostatic obstruction, and in no case should a surgeon stand by and use simple palliative measures when a radical operation performed early will save the patient long and indescribable suffering.

A NEW MATERIAL FOR SURGICAL SPLINTS AND JACKETS, WITH A METHOD FOR APPLYING IT.

Read in the Section on Surgery and Anatomy, at the Forty-fourth Annual Meeting of the American Medical Association.

BY EDWARD A. TRACY, M.D.

BOSTON, MASS.

This material, in its crude form, is old as the hills—for the members of the energetic wasp family have used it, time out o' mind, in the construction of their homesteads. I refer to wood pulp.

There are many varieties of pulp board on the market, and to give their characteristics in detail would needlessly take up your time; suffice it to say they were tried and found wanting. The needful combination of properties sought for was plasticity, toughness, elasticity and rigidity. It took some experimentation to get the desired product, but my task was lightened by consulting my friend, Mr. Charles H. Fish, of Manchester, N. H., a gentleman familiar with every branch of pulp manufacture.

more complex splints, as of the elbow, shoulder, spine, or pelvis, it is serviceable to first cut a pattern of cloth or paper laid over the part in the position it is intended to retain it, and afterwards, with this pattern for a guide, the proper shaped blank can be cut from the sheet of pulp board. The splint-blank should be moistened (best done by means of a brush) with water, or a stiffening solution, just enough to render the material plastic; then it should be carefully molded over the part, with the aid of a roller bandage; after being so retained for a moment, let it be removed and dried. An accurately fitting splint results.

Of the various stiffening solutions tried, that of potassium silicate gives particularly good results. The solution ordinarily sold for surgeons' use and further diluted with water (10 to 50 percent, according to the rigidity desired) can be conveniently used. This solution hastens the drying process, adds rigidity to the splint, prevents perspiration from softening it, and renders the splint antiseptic. These facts are illustrated in the specimen shown, a splint made in fifteen minutes for a case of compound fracture of the right forefinger; during a part of the time it was worn, its distal end was plunged thrice daily into an antiseptic solution and you can witness how it withstood the treatment. (See Fig. 4.)

A solution of dextrine serves well, adding toughness and stiffness to the material. It is convenient for the general practitioner because dextrine (to be had of paint wholesalers) can be kept in powder form and

Fig. 1.

The experiments made, and the manufacturing processes employed, might form matter for interesting discourse in the laboratory and the mill; I do not propose to claim your attention for them here, but shall place directly before you a sample of the finished material, and explain how the practical surgeon bends it to his will and produces therefrom a good surgical splint.

A sheet of the material is taken and the splint-blank of the shape intended cut from it. Ordinary arm and leg splints can be outlined immediately on the pulp-sheet and cut without other pattern. For

Fig. 2.

Fig. 3.

Fig. 4.

a solution extemporized at any time. Good results are gotten with water as a moistener, and I recall an emergency case treated last winter where with it, a kitchen fire, and a piece of this pulp board, an excellent splint was made in half an hour for a severe injury of the ankle. The splint was worn for three weeks.

Now that the practical working of the material has been touched upon, a glance at the possibilities of its future use may be permitted me.

An illustrious member of this Association, Dr. Marcy of Boston, struck the keynote on seeing one

of my earlier splints: "The surgeon must make a splint to fit the limb—not the limb to the splint."

For leg, arm and finger splints, it requires no special skill to obtain superior results with my material. A study of the accompanying illustrations will indicate this. No. 1 is that of a splint for fixation of the left thumb, including its metacarpal bone. No. 2 shows an anterior knee splint for making immobile the knee joint; with a reinforcement controlling the quadriceps femoris it may prove useful in fracture of the patella. No. 3 represents a splint molded over the inner side of the right arm as it hung limp by the body, the palm against the thigh.

In complex cases the genius of the surgeon and his handiwork can shine forth in the creation of apparatus suitable for the case.

Apparatus heretofore impossible or rare because of its cost or the necessity for employing skilled tradesmen, will become plentiful.

Finally, knowing the properties possessed by this material, it requires but little foresight to comprehend the evolution in the near future of radically new apparatus for the treatment of various surgical affections.

In concluding, I feel happy to here express my hearty acknowledgment and thanks for suggestions and kindnesses tendered me by Drs. H. P. Bowditch, M. E. Gay, G. W. Gay, H. M. Marcy and D. W. Cheever of Boston; also, to Dr. W. M. Couant, who very courteously placed suitable hospital cases at my disposal, when experimenting on the material.

ON SOME POINTS CONCERNING CLUB FOOT.

Abstract of a clinical lecture delivered at the Children's Hospital, Great Ormond Street, London, May 11, 1905.

BY EDMOND OWEN, F.R.C.S.

SURGEON TO THE HOSPITAL, LONDON, ENGL.; SURGEON TO ST. MARY'S HOSPITAL.

[ABSTRACTED BY A. M. PHELPS, M.D., NEW YORK.]

Mr. Owen recognizes the two forms of equino varus, viz: the congenital and acquired, and also calls attention to the fact that one variety is much more easily cured than the other. He inclines to the belief that pressure in utero is one of the chief causes of the deformity. I quote:

"Probably, after all, the cause of the congenital deformity is the faulty packing of the fetus in utero. Here I show you a specimen of a fetus taken by surprise, as it were, and removed at about the sixth month. You will notice that the heels are markedly drawn up and the soles turned inwards. Often after a premature labor we find the feet folded flat upon the front of the chest, and much more inverted than in the specimen I have just handed round. It is a very suggestive fact that no other variety of club foot is found as a congenital defect. Only once have I met with a congenital instance of *talipes valgus*. I suppose the explanation is, that when the fetus is in utero, the muscular walls of the uterus can easily press and invert the feet against the front of the chest, while it is well nigh impossible for the uterine walls to turn the feet with the soles everted. The extreme inversion is evidently to insure the most convenient packing in utero, the fetus could not be snugly packed in utero with the soles turned out in the position of *talipes valgus*."

He teaches that the treatment should be commenced immediately after birth by manipulation

and fixation. "that the various fibers which are binding the foot in a faulty position may be the more easily stretched."

"Here is a boy whose foot illustrates the contraction of the plantar fascia—a case of paralytic equino varus. The case shows only in a moderate degree the double deformity, but it well illustrates the creasing across the sole; by pressing with the finger when the foot is in a somewhat corrected position, you will feel the very tight band which is caused by the plantar fascia. The structures needing attention, then, are the skin, the tendon of Achilles, the tibialis posterior, the flexors of the toes, the tibialis anticus and the plantar fascia. Last, we come to the anterior part of the internal lateral ligament. This is a very obstinate element in maintaining the deformity after the tendons have been divided. Students, as a rule, do not understand the importance of the internal lateral—the deltoid ligament. It is attached above to the internal malleolus, and below it spreads into the sustentaculum tali, and (which is the important point) forward on to the scaphoid bone. As a matter of fact only a comparatively small part of the internal lateral ligament runs to the astragalus; a good deal of it goes to the os calcis, and still more to the scaphoid bone; so that, if the foot has been cramped in the position of equino varus, it is impossible to straighten it out correctly, unless the anterior part of the internal lateral ligament which runs from the internal malleolus to the scaphoid bone is effectually dealt with. (This dissected specimen of a club foot shows the strong, anterior part of the internal lateral ligament holding the foot rigidly against the lower end of the tibia.)"

"I said a few minutes back that it was a matter of great concern to the surgeon whether the club foot which he was called upon to treat was a congenital defect, or the result of a central nervous lesion; the congenital defect being much more amenable to treatment than the deformity which is the result of infantile paralysis. And so marked is the difference in the result of the treatment in these two classes of cases, that there are some surgeons who absolutely refuse to operate at all in equino varus, which is the result of paralysis. No surgeon can get a very brilliant result in such cases, but with vigorous treatment he may get, as I shall show, a very fair one."

In the treatment of babies suffering from congenital talipes varo equino I quote the following:

"As regards the treatment of the congenital equino varus, as soon as the child has been washed the manipulations are to be begun by the surgeon trying to put the foot into an improved position. He will gain a little every time. He takes the ankle in one hand, and grasping the foot with the other, he flexes the foot; that is, he brings down the heel, and he gently but firmly everts the foot. Every time he goes to see the mother he must resort to this little maneuver, and he must also get the monthly nurse to help in the intervals of his visits. Three times a day, or oftener, the nurse is firmly to flex the foot; and little by little the skin and the ligaments and the tendons will yield, and the foot will come into the improved position."

"Should the case be neglected, it will return to the hospital with a relapse."

"The mention of this word 'relapse' causes me to make a remark in connection with the treatment of club foot; you hear, or at any rate I hear sur-

geons of experience in connection with club foot, say that they never have, or have had, a relapse after treatment, and that they would be ashamed if any of their cases did relapse. When I hear them publicly talk like this, my thoughts revert to Ananias. Relapses there must be in the treatment of club foot, unless the surgeon is constantly watching over the case day after day and week after week, and it may be year after year; and how rarely can this effective supervision be insured. Relapses there are and must be in the practice of every surgeon.

"I never see relapses in cases which I am permitted to handle after operation."

"But to return: The treatment of the simple congenital defect consists, then, in manipulation—vigorous, it may be—so that the anterior part of the internal lateral ligament and other structures may be well stretched. But suppose after several months of this procedure, although the gain is considerable, it is insufficient—something else must be done; and that should be subcutaneous section of the tendon of Achilles. It is inadvisable and useless for the surgeon to struggle against this strong and resisting structure. If he finds that he is not making sufficient progress, let him divide it first and foremost, and he will then obtain a fresh start. If you turn to your works on orthopedic surgery you will find it advised that section of the tendon of Achilles should always be left to the last division; but I say, let this tendon be divided *first* of everything, as it is the most important element in holding the foot in the wrong position."

He explains correctly that division of the tendon of Achilles not only allows the heel to come down, but also the inversion is overcome. I quote:

"Possibly I have not made myself sufficiently clear. Let me show what I mean upon this case. Here is the tendon of Achilles running to its insertion, the heel being in the mid-line. The contraction still takes place in the tendon of Achilles, and the heel, which is fairly movable under the astragalus, becomes rolled inwards. This is not theory, it is an actual fact; and when in these cases the tendon of Achilles is divided, not only does the heel come down, but the inversion is corrected."

"How do you know that any individual case of equino varus that you have to treat, is not one of those cases in which simple division of the tendon of Achilles may not effect so much improvement? Divide the tendon of Achilles first and see. That is the only way to find out. I stand by the assertion that the tendon of Achilles should always be divided first, when we are operating for equino varus. Sometimes this simple tenotomy suffices in the way of operation; often other tendons have to be divided as well."

Mr. Owen graphically pictures a case treated by subcutaneous work in the following words:

"Let us in our charity suggest it is a case of relapse, a case which has been under somebody else, and the child is four or five years old. Evidently manipulations, frictions and massage will not suffice for the effacement of the remaining deformity. The tendon of Achilles is to be divided first. Then, perhaps, the tendon of the tibialis anticus and that of the tibialis posticus, subcutaneously, if you will; and subcutaneously the plantar fascia shall be divided; and subcutaneously everything else shall be divided which prevents your getting the foot into

the improved position. But in my experience this subcutaneous surgery has not been altogether satisfactory. In any case, for instance, the skin prevents due unfolding of the foot. Of course if a surgeon asserts that he never has a relapse, and that he resorts to no more severe method of treatment than that of subcutaneous division of these structures, then I shall say, granting that all he says is true, by all means let him continue; but my experience in hospital practice, and especially with the out-patient class, is that subcutaneous operations do not effect enough. How, then, is a case of relapsed or neglected club foot to be dealt with? You shall perform the subcutaneous divisions of tendon and fascia, if you will, and in a slight case this operation will suffice.

"I remarked a little while ago that the skin formed a considerable element obstructing the reduction of the double deformity; and it was partly in recognition of this fact that Phelps of New York suggested an extremely radical measure in the treatment of talipes. Recognizing the fact also that the days are fortunately past in which open wounds are followed by inflammation, suppuration, or some form of blood poisoning, Phelps boldly suggested that a free incision should be made into the inner border of the sole of the foot, and that every structure which opposed itself to the perfect correction of the deformity should be thoroughly and effectually divided. This open operation of Phelps' is the operation which I am performing a good deal in connection with these cases—not, of course, in the treatment of every young child, or of any child with a slight deformity, but in the case of a child with a neglected, or an extreme deformity. And I am anxious to advocate it as warmly as I can to-day. I have never found any occasion to regret having resorted to Phelps' operation; but on the contrary have every reason for speaking of it in the highest terms. It is performed as follows: The tendon of Achilles is of course first divided, and, with a good deal of brute force, the surgeon does his best to get the foot into the improved position. A vertical incision is then made on the inner side of the foot a little in front of the internal malleolus, over the head of the astragalus. The incision will probably expose the internal saphenous vein, and this is sometimes divided in the operation, though sometimes the surgeon is able to complete the operation without dividing it; but if it is cut it is no great matter. After that he divides the tibialis anticus and, in the lower part of the incision the tibialis posticus, as it runs round to its insertion."

"The plantar fascia is then cut and some of the abductor of the great toe, and then, deep in the sole, the surgeon meets with the long flexor of the toes. Then, using some force still, he improves the position of the foot. Proceeding further he cuts the anterior part of the internal lateral ligament, at the same time exerting more energy upon the foot, and making a wide separation between the head of the astragalus and the scaphoid. Thus he is enabled to get the foot into the straight line, and, breaking through any remaining fibers that resist, he bends the anterior segment of the foot right back, opening the calcareo-cuboid joint, in all probability. When he is satisfied that nothing remains to impede the easy effacement of the deformity, he gently fills the gaping wound with mercuric gauze, and encloses the foot in lateral splints of house flannel which have been soaked in creamy plaster of Paris. In fixing up the

foot it is by no means necessary to use force or restraint, for no resisting elements remain. It is advisable in fixing the foot to have the deformity over-corrected, trusting to the growth of granulation tissue to fill up the wedge shaped cavity. Sometimes the dressing has to be reapplied next day, but as a rule, the foot remains undisturbed for ten or fourteen days. In some cases, indeed, I have allowed a longer interval to elapse before disturbing the first dressing."

In my earliest operations, I was half afraid lest the anterior segment of the foot should slough, but I have never had such apprehensions realized. In fact, it looks as if it might almost have been by design that the large artery of the foot, the external plantar, was specially placed along the outer part of the sole so that it might offer no hindrance to the surgeon who contemplated a resort to Phelps' open method of operating for talipes equino varus. In the course of eight weeks—more or less—the wound is quite healed, epidermis has grown over its surface, and the mass of granulation tissue which filled the space is being converted into strong fibrous tissue for the consolidation of the foot.

"I must just briefly allude to other operations. Possibly next time I shall have to say more on this subject, but merely for the sake of making comparison between Phelps' operation and the other operations which pass under the name of tarsotomy—cutting out a piece of the tarsus. In Phelps' operation nothing is cut away. But in the operation of tarsotomy it may be that the cuboid is removed, or that a wedge is taken from the outside of the foot, the base of the wedge being outwards and implicating various bones of the foot. Or it may be that the astragalus is taken away, so that the structures running from the leg to the foot are slackened, and that the os calcis may fall into its position between the two malleoli. But whichever of these forms of tarsotomy is adopted, there is—there must be—a considerable loss of tissue, for the improvement in the position of the foot is effected by a shortening of the external border of the foot. But in Phelps' operation the improvement is effected by the sacrifice of no tissue whatever, but by the insertion of a wedge of space, as it were, on the inner side of the foot. Thus, when the various resisting structures have been divided, a large gap exists between the head of the astragalus and the posterior aspect of the scaphoid bone."

"I show you here a boy whose case was most unpromising for any operation for talipes: the boy with infantile paralysis on whom I was demonstrating a little while ago. Unfortunately, I have no cast or figure to show the position in which the foot was before his operation. Kindly take my word for it that the deformity was extreme and the prospect unpromising. I performed Phelps' operation upon the foot, dividing everything, and now we have the foot in a very fair position: I think we may say a very excellent position, with no inclination whatever to relapse. Now I am sure of this, that no subcutaneous operation could have effected such an improvement as this open operation has effected, and no tarsotomy could have brought about so great and real an improvement, because in that operation the foot is necessarily robbed of most important elements. The result in this case, so far as it goes, is extremely satisfactory. On being made to walk the

patient gets his foot very flat, as you see. A most important point in this operation, and one on which Phelps insists very strongly and rightly, is that the malposition must be *over-corrected*. Relapse is not very likely to take place, but if you get (if I may use the expression) well to windward of the defect, it matters less if contraction does take place. It is a little heterodox to say that after an operation on club foot the foot should be put in the over-corrected position. In the textbooks you will probably find the advice still given to put up the foot in the old position for a certain length of time, so that the plastic effusion which takes place between the cut ends of the tendon may be gradually stretched. But the answer to that is that the ends of the tendons should be as wide apart as possible, that the little inflammation which is set up by the operation will be followed by the formation of a certain amount of granulation tissue, that this granulation tissue will be converted into fibrous tissue, and by this means a sufficiently long splice may be put into the tendon; and not only a longer splice than you would get if you put up the foot in the old position again, but a stronger splice. If you were putting the foot up in the old position and then gradually stretching the union between the cut ends of the tendon, with each stretching you would be sure to get an attenuation of the uniting mediums and a weakening of the tendon. You would get a less strong band of union between the cut ends than if you boldly and at once put the foot up in the over-corrected position."

"Here is a baby on whom Phelps' operation was performed for double congenital equino varus. Now it is said, and I think very fairly, that in a young child so severe an operation as that of Phelps should not be resorted to. I think it is fair criticism, but I will say that if Phelps' operation is going to give a favorable result in a biggish child, why should it not be resorted to in the case of a little child? In *every* case of a little child I would not resort to Phelps' operation; but here is a very little child, not a year old, with double equino varus, on whom I did perform Phelps' operation on each foot, and see how strong the feet are, and in what a very satisfactory position they remain. This child I have seen nothing of since it left the hospital after the operation months ago; that is to say, there has been no after treatment needed. There is nothing like a flail-like condition in the feet. They are quite solid. If we had done a simple subcutaneous tenotomy in this case, and sent the child away, the mother or friends would not have been able to look satisfactorily after the child, and in all probability, relapse would have taken place. My experience has been mostly with hospital patients. There are other surgeons who deal chiefly with private patients, and of course they can have them longer under supervision, and show excellent results with subcutaneous tenotomy. But, by the hospital surgeon, the open operation has but to be practiced to be appreciated."

"What about a Scarpa's shoe? It is quite out of date. If it is used, unless the child is seen almost every day, it will almost certainly give rise to an excoriation or a sore place. Plaster of Paris is far better. But in the early cases the less, if any, retentive apparatus, the freer the leg and foot, the better for the subsequent development."

"Here is a boy sixteen months old, and these are casts of his feet before operation. The case is not

now quite so satisfactory. On the right side there is still a little inversion, notwithstanding all the structures named having been divided. The inversion which persists is, I think, sure proof that after Phelps' operation a limp splay foot is not the result. On the right side, the foot is in a very excellent position, but on the left side, there is just this little inversion, which I believe will be easily corrected by simple manipulation. I do not think that any further operation is needed. I have not seen this child for months."

"It is a point in favor of Phelps' operation, that when you have divided all resisting structures, there can be no more contraction of them. You have done the work and the child will hardly require looking after. As we are going to operate this day week, on this boy (case previously referred to), I shall be able to show exactly the method of treatment; but I may say in passing, that after the large wound has been made, the cavity is generally stuffed with a little mercuric gauze, and that the foot is then fixed in the position of over-correction. I here show you this other boy, operated on two years ago, when he was a year old. This was a case of extreme equinovarus. There is no attempt at inversion here, and the boy, who has had plaster of Paris on, if he could stand could get his foot well to the ground. The foot has nothing like a flail between the anterior and the posterior segment of the foot."

RELIEF FROM PAIN IN LABOR.

Read before the Section on Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY I. N. LOVE, M.D.

PROFESSOR CLINICAL MEDICINE AND DISEASES OF CHILDREN, MARION-SIMS COLLEGE OF MEDICINE; EDITOR MEDICAL MIRROR, ST. LOUIS.

As physicians, we may well ask ourselves if we sufficiently appreciate the importance of saving our patient pain. I will say that pain in the abstract is conservative, that it is the announcement on the part of nature that something is wrong and needs correction, and that we should be very guarded in relieving pain for fear of removing nature's flag of distress rather than removing the cause, but the arguments which will apply to pain which is an evidence of disease are not in my judgment apropos to pain as an accompaniment of parturition.

In the primitive state, undoubtedly woman was possessed with great muscular force and absence of nervous sensibility. Civilization, social customs, modern habits of life have developed the nervous centers at the expense of the muscular tissues, and we have in these latter days women who may truly be termed sensitive plants, whose muscular force is below par and whose nervous systems are "on edge" as it were.

I have made it a rule for many years to insist upon a thoroughly cleared out condition of the alimentary canal upon the part of every woman under my care during the entire term of pregnancy: at the same time I have encouraged elimination on the part of the other excretory organs by the liberal administration of Garrod-Spa water, freely flushing out in this way the kidneys at frequent intervals. The activity of the skin I have encouraged by frequent warm baths at bedtime. This latter has aided in the direction of a greater degree of restfulness which is important.

As every one knows, the average woman is overstipated; doubly so during pregnancy, and there are double reasons for making efforts to remove this condition, because the interests of two people are involved instead of one. When I have evidence that labor is near at hand, I give my patient an increased amount of purgation. Immediately following the termination of labor I again purge freely with a view to the better clearing out of the alimentary canal and the removing of accumulated poisons. When I graduated in medicine, the instruction was given me to wait until the third day after confinement before evacuating the bowels. The same argument presented in favor of purgation as a preventer of peritoneal inflammation following abdominal sections, rather than opiates, will apply to the parturient woman. Constant, careful regard for all of the excretory organs, the keeping of the animated system of sewerage thoroughly cleared out, will in my judgment in the majority of cases eliminate puerperal convulsions from the nosology of the accoucheur. So much for elimination.

Now with regard to the best good of our patient from the standpoint of prevention of pain. We all know that the pregnant woman is prone to having her nervous system out of joint; in fact, the condition in itself is a severe test to the female nervous system. It is needless to recall to your mind how the very beginning of pregnancy is announced in many cases by peculiar nervous phenomena. During the entire term the imagination of the woman often becomes exalted or depressed. Her disposition is irritable. In many cases she is continually between two fires: upon the one side the greatest gloom, upon the other an excessive joy. Suspicion, jealousy, general sensitiveness are present, which under other conditions are never dreamed of. Nervous pains abound, migraine, facial neuralgia, toothache, itching in various parts of the body, together with smarting and other evidence of irritation of the peripheral extremities of the nerves. The most grave nerve troubles sometimes are present; eclampsia, chorea and often mania. Truly we have evidence in favor of the thought that pregnancy is a severe test to the stability of the nervous system.

It is absurd to talk of pregnancy as being a physiological condition; as much so as the eating of one's dinner and the digestion of the same. Under primitive conditions it probably was so, but surely not under the conditions which prevail in this latter decade of the nineteenth century. How many of us have seen the last months of the pregnant woman made miserable by continual aches and persistent pains throughout the abdominal region and other parts of the body where there has been a disturbance of the circulation owing to pressure upon the vessels. Unless this condition of affairs receives attention the average pregnant woman is in poor shape for meeting the ordeal which faces her at the close of her nine months' siege. I consider it our duty to guard the nervous system during this siege as carefully as we have guarded the eliminative organs. We will find that attention to elimination will help us in our service as a pain reliever during these months of trial. The engorgement in certain parts of the body is less; the removal of ptomaines and other poisons, the activity on the part of the secretory system of glands renders the nerve centers less sensitive and less easily demoralized. At the same time

we should save our patient every possible pain during this entire period. The warm baths at bedtime, suggested as aids in the direction of elimination, also favor the soothing of the nervous system and a complete rest at night. Massage given by a skilled masseuse preferably, is beneficial.

The excruciating pains complained of in the lumbar and abdominal regions can be relieved to a marked degree by rubbing the surfaces with a liniment composed of equal parts of chloroform, tincture of iodine, tincture of belladonna, tincture of opium, tincture of arnica and olive oil. If the restlessness and pain be great toward the latter weeks of pregnancy, in spite of the measures suggested, it is our duty to furnish a more positive relief in the form either of a combination of bromide of soda and chloral, ten or fifteen grains each, to be repeated to the extent of securing rest, or even now and then the administration of an opiate. I believe, however, that it is our duty to deliver personally to our patient the remedy desired and not to write a prescription, in order that no knowledge may be had upon the part of the patient as to the nature of the remedy taken and that we may the better limit it. I have occasionally found a dose of ten or fifteen grains of sulphonal or antikamnia of service at bedtime. One thing I insist upon, that my patient shall not know the remedial agent administered.

We will suppose, now, that the period of labor has commenced and that the suggestions previously given have been observed. The first stage of labor is often tedious, particularly in the primipara, with frequent and persistent nagging pains.

I cannot better state my position than by reporting a single case which is illustrative of a large number:

Mrs. R., the mother of four children. Called hastily in the absence of her usual medical attendant, she seemingly anticipating the time by about two weeks. Age 32. Four previous confinements all long continued and exhausting and terminated with forceps, the reason being given that smallness and compactness of build on the part of the patient precluded natural delivery. Had never been given chloroform for the reason that the physician did not believe the patient was a good subject and besides did not believe in giving chloroform in labor. Bowels had not been moved for three or four days. Instructed the nurse to give an ounce of castor oil together with twenty drops of turpentine, to be followed in four hours by enema of two quarts of hot water administered by the medium of a fountain syringe with a large size soft rubber catheter in place of the usual rectal nozzle, the same to be introduced two-thirds of its length, the enema to be repeated unless a large and free action should be secured. Digital examination revealed a natural presentation with a rigid os in the first stage of dilatation. Giving the patient assurance that everything was in good shape and that I desired to give her a good night's rest, I administered one-fourth of a grain of morphia, hypodermatically, together with fifteen grains each of bromide of soda and chloral by the mouth, the latter to be repeated in two hours. The hour being late and inasmuch as the usual attendant of the patient was absent and she was extremely anxious and nervous, I decided to remain during the night and asked that I be shown to my room. This was 11 o'clock. At 8 o'clock in the morning I was awakened and informed that no services were needed. Two or three liberal actions had been secured from the bowels; the patient had rested in spite of this interruption comparatively well, sleeping a good part of the time; occasionally disturbed by an unusually severe pain. The rest, however, had been pronounced. Digital examination revealed a complete dilatation and the second stage of labor well advanced. The pains soon became very frequent, long and severe. The bearing down resorted to. At once commenced the administration of chloroform, proceeding it by a stiff toddy, giving free inspiration during the pain with a good mingling of air. Relaxation was rapid and the obtundity of pain produced by the chloro-

reform was profound and this assisted the disposition to bear down and within an hour an unusually large child, the first boy, was born. Placenta followed soon afterwards. Contraction of the uterus was complete. The patient gave assurance of the fact that she had never had so easy a time; that she had hardly known what pain was. It will be observed that the forceps were not necessary. Another purgative dose of oil was immediately ordered and instructions given to the nurse to give a small dose of bromid and chloral if necessary to secure rest during the day.

The patient from the beginning was given whatever she wanted to eat, bearing in mind only that excessive quantity should not be given at any time, owing to the fact that digestion would not be as energetic in bed as in health; in other words, the puerperal state does not preclude good food. The patient ought to be extra well fed in order to build up against the long drain and pressure under which she has labored; besides she has to meet an emergency in the direction of feeding two people instead of one, and this should be constantly remembered. Within five days she might safely have sat up. Suffice it to say that she made the best recovery in her experience. She thrived and her baby thrived better than ever before. It is needless to say that she from this time forth was a convert in favor of elimination, tranquilization, rest and freedom from pain, together with the best of food as a series of essentials to the successful emergence from the puerperal state.

I close this rambling paper by presenting the following conclusions:

1. Every pregnant woman throughout the entire period of her pregnancy should have the most careful attention given to her organs of elimination and to proper exercise.

2. Her nerve force throughout the ordeal must be economized, and particularly is this necessary during the last days and hours of her engagement.

3. The well being of herself and her child is involved in this matter of elimination, exercise and tranquilization.

4. Rest is the great encourager of repair as well as growth; repair to the exhausted force of the woman, thus assisting the proper growth of the unborn child.

5. Pain long continued is dangerous, particularly to those not well endowed by nature for the bearing of pain, and as we never think of ignoring the element of shock in our surgical injuries, no more should we ignore it in the parturient state.

6. The rasping destructive injury to the grosser tissues of the human body are often observed by all surgeons. The more complete the surgical management of the case, the completest possible rest after the injuries favors the completest healing, and yet scars may remain.

7. We should save the nervous systems of the mothers of the world from the rasping, destructive traumatism produced by labor, and at the same time we should favor rapid repair, never losing sight of the fact that while the healing may be complete, scars yet remain, and in nerve tissues are much more difficult to recover from and are accompanied by greater interference with proper performance of function than in other more vulgar tissues.

8. Balm sleep is not only "tired nature's sweet restorer," but also the restorer of burdened, fretted, fagged out, wounded, wrecked nerve structures.

9. Graves, the great Irish physician only asked that there be placed upon his epitaph, "He fed fevers." Every thoughtful, warm-blooded, scientific and helpful physician might well ask that there be placed upon his tomb the epitaph, "He gave to his beloved sleep; he saved his patient from pain; not recklessly but intelligently, judiciously, thoughtfully, humanely."

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, IN LIVING POSTAGE,
PER ANNUM, IN ADVANCE, \$3.00
SINGLE COPIES, 10 CENTS

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
501 N. WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the
Treasurer, RICHARD J. DUNGLISON, M. D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, AUGUST 26, 1893.

JEAN MARTIN CHARCOT.

Throughout the civilized world, wherever the language of medicine is understood, there is sincere regret that CHARCOT is no more. This distinguished medical man was graduated in medicine at Paris in 1853, and died at Morvan, France, August 17, 1893. He was director of the great Hôpital La Salpêtrière at the time of his death, in which institution he had been interne forty years ago. His residence was in the ultra fashionable quarter, the Faubourg St. Germaine.

He early commenced the study of difficult questions, turning his attention especially to diseases of the liver and spinal cord. The list of his works in the Index Catalogue is a long one, and the less elaborate studies will be found scattered throughout neurological literature.

The current press dispatches from Paris give the following general statement:

"He organized in 1879 an anatomo-pathologic museum, a laboratory with photographic apparatus, hydrotherapeutic rooms, and began with a series of lectures a clinical course on nervous diseases which has been translated into all the living languages. In 1883 he was a member of the Académie des Sciences, a member of the Clinical Society of London, and frequently received applications for consulting visits from the courts of Europe.

Locomotor ataxia, St. Vitus' dance, hysteria, hypnotism, an infinity of disorders and apparently mysterious effects, received from his patient investigations unexpected enlightenment. His pupils adored him. Marks of distinction were literally showered upon him from sovereigns and learned societies of all nations.

He retained an admirable faith in science, despite the disillusion which were inevitable. He found pleasure only in the thought that he might contribute a stone to the mysterious edifice which would be completed in the distant future.

He published in 1853 "*Etudes pour servir à l'histoire de l'affection décrite sous le nom des nodosités des jointures, goutte Asthenique primitive, rhuma-*

tisme articulaire Chronique," and in 1857, "*De l'Expectation en Médecine*;" in 1860, "*De la Pneumonie Chronique*;" in 1867, "*La Médecine Empirique et la Médecine Scientifique*," a parallel between ancient and modern methods; in 1868, "*Leçons Cliniques sur les Maladies des Vieillards et les Maladies Chroniques*;" in 1873, "*Leçons sur les Maladies du Système Nerveux*;" in 1875, a second edition, with plates and figures, of his work on the diseases of the nervous system; in 1877, "*Leçons sur les Maladies du Foie, des Voies Biliaires et des Reins*," and numerous essays in the *Archives de Physiologie*, of which he was a director.

His capacity for incessant labor was amazing. In 1878 he produced the "*Iconographie Photographique de la Salpêtrière*;" in 1880, a great treatise on "*Les Maladies du Cerveau*;" in 1881, a study of "*L'Albuminurie*;" in 1884, another great work on the nervous system; in 1887, in collaboration with RICHET, one of his pupils, who was a skillful artist and is a famous physician, "*Les Démoniaques dans l'Art*."

There is not a serious work on nervous diseases which is not studied with references to CHARCOT. There is not a practicing physician at the present time free of indebtedness to the lessons of CHARCOT.

And to American physicians, it may be added, a visit to Paris will not be the same since CHARCOT has gone. His mastery of his chosen field, his genial manner, his welcome to strangers and his wonderful diagnostic powers, caused him to be much sought by foreigners, and his decease leaves a vacancy not easily filled.

STUDIES OF HEREDITY.

The recent translation and publication of PROF. WEISMAN'S essays upon heredity, and kindred biological problems, has opened anew the very interesting controversy which has centered about his theories. DR. WEISMAN is a professor of physiology and biology at the University of Freiburg, who has for many years made very exhaustive studies of the problems of heredity. His conclusions differ widely from many of the popular theories, and are considered the most scientific and candid studies published. In some of his last essays he points out the errors of his former theories, and the way in which he made them, and asserts that all scientific facts depend on theories which are frequently found to be wrong, and are given up for more accurate hypothesis.

He affirms that theories alone are valueless without a firm basis of facts, and that a collection of facts without some theory of coherence or relation are worthless. Theories are plummets with which to sound the depths of the ocean of unknown phenomena. He claims that his theories of heredity are supported by the present knowledge of this subject, but are open to revision and correction from further study and research.

One of these theories is that the reproductive germ cells are practically immortal and are transmitted from generation to generation without

variation. The substance of the germ cells, the germ-plasma, has remained in perpetual continuity from the first origin of life. The extreme variations to which the organism is subjected, do not alter the germ cells, and reappear in the next generation. The germ plasma or substance of the reproductive cells continues the succession of the species, while natural selection and chemical fluctuations of the molecules of the organism vary widely, changing the individual. Hence the transmission of acquired characters is impossible, for the germ plasma is not formed anew in each individual. He believes that heredity depends on the fact that a small portion of the effective substance of the germ plasma remains unchanged during the development of the ovum into the organism, and this part of the germ plasma serves as a foundation from which the germ cells of the new organism are produced. The germ plasma may be represented as a root stock from which plants arise at intervals, representing the individuals of successive generations. This germ plasma is derived from that which preceded it, and its molecular constitution can not depend upon the individual in which it happens to occur, but such individuals only form the nutritive soil at the expense of which the germ plasma grows. The tendency of heredity of which the germ plasma is the bearer, depends upon this very molecular structure, and hence only those characters can be transmitted through successive generations which have been previously inherited, viz., those characters which were potentially contained in the structure of the germ plasma. It also follows that those other characters which have been acquired by the influence of special external conditions during the lifetime of the parent cannot be transmitted at all.

These conclusions are studied and exemplified in a very conclusive way. The re-appearance of like qualities of parents in the children are explained by environment, nutrition, natural selection and other forces. He urges very emphatically that mutilations and organic defects of the body can not be transmitted, because contrary to the doctrine of survival of the fittest.

The natural tendency is to eliminate and throw out the defectives and degenerates from injury and disease, and it would be opposed to nature to perpetuate them to the next generation.

Lessened vigor, and incapacity to resist adverse influences appear in the children followed by early death. The direct transmission of disease germs which fasten themselves to the sperm or germ cell, and are thus transmitted from one organism to another, are proved to be highly probable facts. The disease of the silkworm is transmitted in this way, and the tuberculosis, syphilis, and smallpox germs, may in all probability follow the same law of trans-

mission. Artificially produced epilepsy is explained in certain cases as following direct from microbic origin which is transmitted in this way. The two parental germ plasmas are very complex substances, and consist of a number of ancestral germ plasmas of different proportions, which combine in different degrees of strength. From these combinations different ancestral forces are increased or retarded; along this line, natural selection separates and breaks up, or perpetuates the germ cells.

Many of these studies and theories have an intense interest to every physician. The author has an exceedingly frank way of presenting his conclusions, and the apparent facts on which they are based; claiming only their probable correctness, and inviting the reader to join with him in farther study. It is evident to the reader that these complex biological theories, are no more fanciful than those which daily confront him in the practice of medicine. Also, if the many medical problems were discussed with the scientific breadth and frankness of this author, we should have less to unlearn and put aside in daily study.

THE YELLOW FEVER.

On the morning of the 10th August the country was startled by the announcement of two deaths from yellow fever having occurred in Pensacola. On July 22 the Spanish steamship *Leonora* arrived; on the 26th a sailor was taken to the hospital; on 27th a second, on 28th a third, on 29th a fourth. Two were discharged, and by the 1st August the two remaining cases had developed into yellow fever; the vessel was then sent to the Gulf Quarantine Station.

This was practically the first announcement for years that the disease had passed beyond the quarantines. The arrival of vessels infected with yellow fever at points on the Gulf and at South Atlantic ports has occurred almost weekly for the last eight weeks. The announcement of the deaths at Pensacola was made by the Board of Health, and even if the Board were mistaken in one case, at least one of the cases was regarded as suspicious by some of the best yellow fever experts in the country. Being thus authenticated, it naturally created a panic and an exodus from the place of all those who could get away; with the consequence of the quarantine of other cities and States against Pensacola; and it looked for a day or two as if the country was going to suffer from "shot gun quarantine" and the horrors incident thereto. The action of the Pensacola Board of Health was in striking contrast with the action of similar bodies previous to 1881, when as a rule efforts were made to hide the existence of a disease, and yellow fever was not pronounced epidemic until more deaths occurred in a week from that disease than from all other causes. One point of the controversy between the

Sanitary Council of the Mississippi Valley and a Board of Health was the non-reporting of the existence of cases in a certain locality, thereby causing a quarantine by that organization against that place.

The States in the Sanitary Council organization in April, 1879, agreed to promptly report the first cases of yellow fever. The American Public Health Association also adopted a like measure in 1884. It was not, however, until Dr. JOSEPH HOLT became President of the Louisiana State Board of Health that the custom became general, as he announced promptly all authenticated and even suspicious cases.

The situation was intensified a few days after the Pensacola affair, by the announcement that Dr. BRANHAM of the Marine Hospital Service had yellow fever at Brunswick, Georgia. Late in June the captain of the bark *Anita Becard*, died of yellow fever on Satula river, near Brunswick. DR. CARTER, of the Marine Hospital Service was sent there to prevent its spread. DR. BRANHAM relieved DR. CARTER, and soon after was attacked by the disease, and on Aug. 19, died. The last time Brunswick suffered from yellow fever (1875) the first death occurred on August 20th. The most experienced yellow fever experts have been in charge for the last two weeks and every possible precaution has been taken to prevent the spread of the disease. As we go to press the dispatches announce another case of yellow fever at Brunswick, and a general exodus from that place in progress.

The highest point north that yellow fever has occurred in the valley of the Mississippi was in August 1854, when a patient came up the river on a steamer from New Orleans to Rock Island, and two nurses who attended him contracted the disease and one of them died. Going farther south in 1873, four railroad laborers at Centralia, who were transferring hides which had been sent from Shreveport, where yellow fever had prevailed, were attacked by the disease. In 1878, one hundred and five refugees from the yellow fever districts suffered with yellow fever in different parts of the State north of Cairo; of these there were twenty-four deaths, the greater portion of them occurring in the city of Chicago—and in not a single instance did those who attended them contract the disease. In that year a number of the attendants at the quarantine station below St. Louis contracted the disease. It is a well established fact that yellow fever will not spread unless there has been a continuous mean temperature of upwards of 70° for some considerable time. It is safe to assume from the experience of the past and judging by the temperature, that yellow fever will not spread this time anywhere north of St. Louis and by September 1st, anywhere north of the Ohio river. Fortunately for the State of Florida, and for the country, that State now has a State Board of Health, and a State health officer of great experience and untiring energy.

ANIMAL EXTRACTS IN EARLY MEDICAL ANNALS.

The modern use of prepared animal organs and animal extracts has probably not yet attained to such therapeutic rank as would lead the Committee on Revision to introduce this distinct class of remedies into the National Pharmacopœia. And yet for such action respectable authority and precedent are not wanting, since in the Dispensatory made by the "College of Physicians" of London, as we learn from the famous edition of "NICH. CULPEPER, Gent. Student in Physick," (of which the second edition was published in 1650), there was an entire section devoted to "Parts of Living Creatures and Excrements," from which possibly some *fin de siècle* clinician might even now obtain a few available hints that might direct his investigations for new specifics, as he will find some curious precedents for those lately brought into use. Thus *Cerebrum* is anticipated in the following: "The brain of Sparrows being eaten provoke lust exceedingly." "The brain of a Hare being roasted helps trembling; it maketh children breed teeth easily, their gums being rubbed with it; it also helps scaldheads and falling off of hair, the head being anointed with it." BROWN-SEQUARD'S *Spermine* is suggested by this note: "Cocks' stones nourish mightily, and refresh and restore such bodies as have been wasted by long sickness; they are admirable good in Hecktick fevers, and (GALEN'S supposed incurable) Marasmus, which is a consumption attending upon a Hecktick fever; they encrease seed and help such as are weak in the sports of Venus." The next is of similar but more potent character: "The yard of a stag helps fluxes, the bitings of venomous beasts; provokes urine and stirs up lust exceedingly." *Cardine* is possibly prefigured in this paragraph: "The bone that is found in the heart of a Stag is as sovereign a Cordial, and as great a strengthener to the heart as any is, being beaten into a powder and taken inwardly; also it resists pestilences and poison." The next might be termed *Pneumonic*: "The lungues of a Fox well dried (but not burned) is an admirable strengthener to the lungues; see the Lohoch of Fox lungues." *Hepatic* is forestalled as follows: "The liver of a Duck stops fluxes and strengthens the liver exceedingly. The liver of a Frog being dried and eaten, helps quartan agues, or as the vulgar call them third-day agues." The next might be termed *Vesical*: "A Sheep's or Goat's bladder being burnt, and the ashes given inwardly helps the *Diabetes*, or continual pissing." Among the peculiar remedies may be noted "Unicorn's horn;" "the head of a cole-black Cat, burnt to ashes in a new pot;" "the skul of a man that was never buried" beaten to a powder and given inwardly; "the fat of a man" used as an ointment and powdered Mummy for internal use.

Suggestions are made elsewhere with regard to the

use of centipedes, woodlice, earthworms, land scorpions, grasshoppers, the flesh of vipers, for various morbid states, with much apparent confidence in their alleged virtues.

Another work which appeared about the same time as the preceding, was, "Health's Improvement; or Rules Comprizing and Discovering the Nature, Method and Manner of Preparing all Sorts of Food used in this Nation." It was printed at "The Sign of the White Horse in Paul's Churchyard 1655," and was written by "that ever famous THOMAS MUFFETT, Doctor in Physick," but it did not appear until after the death of the author, when it was corrected and edited by CHRISTOPHER BENNET, doctor in Physick and Fellow of the College of Physicians in London." From this interesting work we will take but two therapeutic hints: "Pithmarrow running all along from the hinder brain (whereof no doubt it is a portion) to the end of the backbone or chine of beasts, is no doubt much harder and drier than the brain itself, especially towards the further end of the back; which dryness makes it less loathsome to the stomach than brains are; yea, furthermore, it strengtheneth that body which is able to concoct it. Many are of opinion that Cawdles made strong with the pitte of a Steer and yolks of newlaid eggs, do by a secret property restore nature, and recover the weakness of loyns caused by venery. MONTAGNANA maketh a singular confection of divers marrows to that purpose, which I will not set down in English, least wantons be too bold to follow their follies."

Thus history repeats itself, even in therapeutics. Upon reviewing the remedies in use by the leading practitioners of medicine two centuries and a half ago, one can sympathize with the author of "Tristram Shandy," who declared that "the physicians here are the errantest charlatans in Europe or the most ignorant of pretending fools. I withdrew what was left of me out of their hands and recommended myself entirely to Dame Nature."

Possibly the willingness of the Pilgrim Fathers to leave their former homes and settle in the wilderness was in some measure to be ascribed to the medical practice which prevailed in Europe at the time; if so it is highly appropriate in this Columbian year, to make a claim for the tardy recognition of the part which medical science had in stimulating exploration and emigration in the sixteenth and seventeenth centuries.

CHOLERA.

The intense heat that has prevailed in Europe during the past week has caused an increase of cases of cholera, and its spread to hitherto uninfected localities. There are now twenty-six districts infected in Russia, and within the last week there has been a decided increase of cases in Moscow and St. Peters-

burg. The official report for the week past, shows a total of 2,372 cases and 951 deaths. The express train service between Russia and Bulgaria, Turkey and Servia has been suspended. Express trains now run between Belgrade and Paris only. In France there has also been an increase and a marked tendency to spread to the interior from the south. There has also been an increase at Naples, and the disease has spread to Salmoia, Campobella and other villages in Italy. So far but few cases have been found in Spain. The Austrian Government is charged with concealing cases, for commercial purposes, in Hungary. There is undoubtedly an increase in Austrian Galicia. Cholera has also appeared at Brabillio, Solina and Galatz in Roumania. As expected there was an increase of cases at Antwerp. The Imperial Board of Health announces there have been thus far this summer only four cases of cholera in Germany. Three of the persons attacked died. These are reported as having eaten tainted meat imported from districts in Russia in which cholera has prevailed. The following extract from a recent Berlin letter will explain the situation.

"Although the authorities are taking unusual precautions to prevent and suppress cholera, no disturbance of railway or other traffic is apparent. Only the emigrants from the stricken districts of Russia are disinfected. If the emigrants are destitute they are sent at the public expense to America or elsewhere. The orders to turn back all destitute emigrants trying to cross the Russian frontier have failed to accomplish much. By one kind of fraud or another the steady stream across the border is kept in motion.

In Berlin the emigrants are swindling the Relief committee and other people ready to help them. No matter how much money they show at the border to facilitate their admission to the country, they are likely to delare themselves destitute as soon as they reach Berlin in order that they may have their expenses paid."

At Bremen the embarkation of Russian emigrants on the North German Lloyd steamships has been prohibited. This should have been done before. Why should this country receive immigrants from cholera infected countries? We are constantly running the risk of cholera, at the same time adding thousands to our already great number of unemployed. While it is true great precautions are taken, still there is danger.

Upon the whole the situation is favorable, particularly when it is taken into consideration that there are so many places that are infected, and with the exception of Russia, the disease is practically controlled by the extraordinary efforts made by the different governments. Cholera is thus shorn of much of the suffering and loss of life which has heretofore followed in its track. The probabilities are that within a short time there will be a decrease of the pandemic.

No new cases occurred among the *Karamania's* passengers quarantined on Hoffmann Island, and the same were discharged after being there eighteen days. There is still danger, and there is still need for vigilance. The American quarantine system is on trial.

DISINFECTION OF PHTHISIC SPUTA.

With the progress of bacteriological knowledge, come the various practical suggestions that make such knowledge useful to mankind in preventing the spread of infectious diseases, and rendering them less virulent. It is now well known that the phthisical sputa is the principal means of propagation of tubercle, outside of the body. Clinical observation long ago demonstrated that persons in close personal contact with phthisics for a protracted period of time were extremely liable to contract the disease, and now that we know the cause, we should quickly employ effective means of destruction of the fatal bacilli.

REMOUCHAMPS (*Revue des Sciences Medicales*, July, 1893), has employed carbonate of sodium in boiling water as a cheap and practical means of destroying the tuberculous contents of spittoons and particularly of handkerchiefs. He demonstrated its efficiency by an experiment as follows:

On some squares of linen he spread the expectoration from phthisical patients and demonstrated the specific bacilli in great abundance. After drying, he placed these cloths in a vessel and sprinkled them thoroughly with soda carbonate, and poured on them two liters of boiling water, in which they remained during the night. The next morning he expressed the contents of the linen squares into a glass vase. Three guinea pigs received an intraperitoneal injection of two cubic centimeters of the liquid taken from the bottom of the vase. Four months afterward neither of the three animals had become tuberculous.

This principle is used in several of the European hospitals in the disinfection of spittoons. BARD (*Revue des Sciences Medicales*, July, 1893), has invented a sort of galvanized iron wire grate capable of holding sixteen spittoons. These are placed in a tank of boiling water for eight to ten minutes, and they require no watching or special attention. BARD believes that carbonate of soda is unnecessary.

In phthisic wards, dry sweeping should not be practiced, for it is well known that sweeping may put dried sputum in suspension in the air. When a wooden floor is necessary for such wards, the joints should be kept well calked with some terebinthinate substance or frequently kerosened. The parquet floors are superior to any other, as they have no open crevices. The use of the broom should be forbidden. Frequent washing the floor with antiseptic solutions and drying with the squeegee will be found useful. The squeegee, as is well known, is made of a piece of wood having a strip of rubber set in a groove in its under part, and well mounted on a handle.

Handkerchiefs used by phthisics should be well powdered with carbonate of soda and plunged in boiling water for ten minutes, after which, at con-

venience, they may be safely sent to be laundered with other linen.

SPECIAL TRAIN OF THE JOURNAL.

The special train of the JOURNAL OF THE ASSOCIATION for the Pan-American Medical Congress will leave Chicago at 8 A. M. Sept. 3, from the new Illinois Central depot, 12th St. and Park Row. Buy your tickets over the "Big 4" at the excursion rate announced elsewhere. The railroad company promises that the accommodations of this train will be the best they can furnish.

HEALTH OF CHICAGO FOR THE FIRST THREE WEEKS IN AUGUST.

Week Ended:	Total Deaths.	Under Five Years.	Death Ratio per 1,000.	Modern Cholera.	Other Infections.	Other Diseases.	Diphtheria.	Scarlet Fever.	Rubeola.	Cerebro-spinal Meningitis.	Whooping Cough.	Phthisis.	Pneumonia.	Brachitis.	Diarrhoea.	Faetor Fumens.	Parotitis.
August 5	69	39	21.92	151	56	11	6	18	5	1	9	4	15	6	1	1	1
" 12	74	35	21.59	185	52	11	8	8	7	1	10	12	9	12	1	1	1
" 19	63	35	18.78	208	2	15	11	11	1	1	4	8	9	18	1	1	1

From the foregoing it will be seen that the health of Chicago for the three weeks under consideration has been very good, especially for the last week. In fact, in no year for the last twenty-five has the death rate been so low for the time under consideration. The health of the other large cities of the country is also good at this time.

SOCIETY NEWS.

The Association of Military Surgeons of the National Guard of the United States.

Abstract of the Proceedings of the Third Annual Meeting, held in Chicago, Ill., August 24, 25, and 26, 1893.

(Continued from page 287.)

THIRD DAY—MORNING SESSION.

Dr. CHARLES B. EWING, U. S. Army, read a very interesting paper entitled

THE SELECTION OF THE SOLDIER.

in which he drew the following conclusions:

1. That the rules and regulations governing the examining surgeon in the physical examination of the recruit, be separate and distinct from those that govern the recruiting officer, who is not a medical man.
2. That the room in which the examinations are made should not be less than twenty feet square, well lighted and ventilated.
3. That the unit of measure be as small as possible, and that the metric system be used.
4. That the recruit be measured in the horizontal instead of the upright position, as at present, so that the large number of men now rejected as being below the standard be saved to the service.
5. That this method of measurement be used so that the exact value of height be obtained in its relation to the other physical equivalents of age, as they are governed by nativity.
6. That weight be determined by a uniform system, the

metric, and that the apparatus consist of scales of the simple bar and weight pattern rather than the old style.

7. That special pains be taken to fix the physical equivalent, so that its proper relation to height, weight and age can be determined for each separate nationality.

8. That the chest girth be changed to conform to the present standard of weight and height.

9. That special attention be given this, so that proper ideas may be obtained in the relations of this physical equivalent of weight, height and age, as it affects each particular race in this country.

10. That data be collected from our present statistics in relation to age, weight, chest girth, chest expansion and capacity, of each separate nationality, so that a better and more exact basis of selecting the recruit can be made.

11. That the spirometer or some modification of it be used as an aid in determining vital chest capacity, also that callipers be authorized so as to measure depth of chest.

12. That the present method of determining hearing be modified.

13. That the test for vision be changed, and that the prismometer be placed in general use for the determination of simple refractive defects.

14. That it be no longer obligatory to determine with such exactness the age and size of piles, but that this condition be left to the discretion of the surgeon.

15. That the paragraph relating to varicocele be expunged, as our present instruments of precision can not measure the fine pathological distinctions insisted upon.

Dr. FRANK R. KEEFER of Fort Stanton, N. M., contributed a paper entitled "Observations on the Physical Examination of Recruits," which was referred to the Committee on Publication, without being read, in the absence of the author.

THIRD DAY—AFTERNOON SESSION.

At this session it was decided to publish a monthly Military Medical Journal, to be devoted to the professional interests of the Army, Navy, Marine Hospital Service and National Guard of the United States. The publishers to be the F. A. Davis Company of Philadelphia.

Dr. CHARLES SMART, U. S. Army, contributed a paper on
THE MEDICAL DEPARTMENT OF THE ARMY.

which was read by Dr. B. J. D. IRWIN, U. S. Army, in the absence of the author.

The great war of the rebellion demonstrated that an efficient system for the care of the wounded was one of the grand divisions of military sanitation, and continued efforts have been made to build up our methods on the foundation of experience which was then gained; that war enlarged our views, and it lasted long enough to enable us to develop a system based upon the enlargement, and to show us what was needful to the successful carrying out of the system. We began the war with methods that were borrowed from Europe. We ended with methods that were developed by the cries of our wounded for relief.

In 1887 a law was passed establishing a hospital corps, and since then the best energies of the department have been devoted to perfecting the organization of this corps and formulating methods by which it will accomplish its work, not only under conditions of peace, but under those of Indian or of modern warfare.

A paper was read on

THE DIAGNOSIS TAG IN THE FIELD.

by Dr. VALERY HAVARD, U. S. Army. The diagnosis tag conspicuously fastened to the clothing of the patient shows at once that he has already received first aid. The brief entries written upon it give further information as to the identity of the patient, the nature of the disability, and the treatment pursued. But these entries, doubtless written in a hurry, are perhaps not very legible; they may have been defaced by blood, rain or dirt, hence the necessity of using a tag that will give as much information as possible at a glance and independently of any writing upon it. For this purpose colors seem to be most useful. In the French, German, Italian, and perhaps other European armies, two kinds of tags are described, one white, the other red. The

white tag denotes that a patient is so desperately wounded as not to be transportable; the red, that the patient can stand transportation. Thus, a look at the tag gives an idea of the gravity of the injury, and to some extent of what can be done with the patient. The author's tag consists of a white and two colored borders; on the body are the printed headings of the entries to be made; the borders are separated from the body by a perforated line so as to admit of being very easily torn off. The left border is red, and the right blue. On the red is printed "transportable," and on the blue "not transportable." In case of a simple flesh wound, whether the patient is or is not able to walk, both colored borders are torn off, leaving only the white body of the tag. If a man is severely wounded, unable to walk, but able to be transported, the blue border is torn off, leaving the red. If a man is desperately wounded and cannot be moved without extreme danger to life, the red border is torn off leaving the blue.

Dr. LAWRENCE C. CARR of Ohio National Guard, Cincinnati, followed with a paper on

THE QUALIFICATIONS FOR AND THE STATUS OF A MEDICAL OFFICER IN THE NATIONAL GUARD.

He said but two States in the Union required any qualification from a surgeon of the National Guard. All that is necessary in the other States is for the commanding officer to suggest the name of some one in his discretion to the Governor. Another factor was the great lack of courtesy from the heads of the military departments of different States to officers in other States, tending to impair the service. It does not seem to be the policy of the War Department at present to allow the regular service and the National Guard to come in contact.

Dr. CHARLES E. WOODRUFF, U. S. Army, read a paper entitled "Military Medical Problems."

Dr. A. H. OUDMAN-DUMESNIL of St. Louis, Mo., read a short paper on

THE PREVENTION OF CUTANEOUS PARASITIC DISEASES IN SOLDIERS,

in which he said the recruit should take a full bath and after this a careful inspection of his body made. His hair should be cropped close and always kept so. His clothing should be changed as often as compatible with circumstances, and should not only be washed but subsequently subjected to dry heat so as to thoroughly sterilize it. Such an operation can be easily carried out and will insure thorough cleanliness. The bath should be taken at least once a week, and upon each occasion the surgeon should inspect the soldier before he is permitted to assume his clean clothing. After the bath a light sponging of the entire body, scalp and face should be made with some antiseptic. Under no excuse should soldiers be permitted to escape the bath, disinfection and subsequent inspection. Infected cases should be treated immediately and segregated, thus removing to a distance the focus of infection. The observance of some such method would practically free a body of soldiers of filth, vermin and parasitic disorders, and, at the same time contribute to making them more alert, attentive to their duties, more efficient and cheerful and correspondingly better disciplined.

The last paper on the program was read by Dr. GEORGE H. HALBERSTADT of Pottsville, Pa., entitled "Camp Cooking Stoves."

The following officers were elected:

President—Col. N. Sonn of Chicago.

First Vice-President—Col. B. J. D. Irwin, U. S. Army.

Second Vice-President—Col. Louis W. Reed, of Norristown, Surgeon General of Pennsylvania.

Secretary—Col. E. Chaney of St. Louis, Mo.

Treasurer—Major Lawrence C. Carr of Cincinnati, O.

A vote of thanks was extended to the Illinois State National Guard, to Dr. and Mrs. SESS for the admirable manner in which they entertained the members of the Association; after which the Association, on motion, adjourned to meet in Washington, D. C., the first Tuesday in May, 1894.

American Electro-Therapeutic Association.—The following is the preliminary program of the American Electro-Therapeutic Association, which will hold its third annual meeting in Chicago, September 12, 13, and 14:

Discussion 1—1. "What are the Possibilities of Electricity in the Treatment of Fibroid Growths." Discussion will be opened by Dr. J. H. Kellogg of Battle Creek, Mich. The

following among others have been asked to take part: M. le Docteur Georges Apostoli of Paris; M. le Docteur Georges Gautier of Paris; Dr. La Torre of Rome; Dr. Augustine H. Golet of New York; Dr. A. Laphorn Smith of Montreal; Dr. Franklin H. Martin of Chicago; Dr. Margaret A. Cleaves of New York; Dr. G. Betton Massey of Philadelphia; Dr. George F. Hulbert of St. Louis; Dr. E. L. H. Metcalfs of New York.

2. "The Influence of Frequency of Interruptions and Character of Induced Current Waves upon Physiological Effect." Discussion will be opened by Professor J. W. Morton of New York. The following among others have been asked to take part: M. le Prof. d'Arsonval of Paris; Prof. Du Bois Reymond of Berlin; Mr. Newman Lawrence of London; M. le Docteur Larat of Paris; Prof. Edwin J. Houston of Philadelphia; M. le Docteur Apostoli of Paris; M. G. Weiss of Paris; Dr. W. J. Herdman of Ann Arbor, Mich.; Mr. J. J. Carty of New York; Dr. J. H. Kellogg of Battle Creek, Mich.; Dr. A. H. Golet of New York; Dr. S. Weir Mitchell of Philadelphia; Dr. A. D. Rockwell of New York; Dr. Frederick Peterson of New York; Dr. W. F. Hutchinson of Providence, R. I.; Dr. Georges Gautier of Paris; Dr. Franklin Martin of Chicago.

Papers:—"The Nutritional Effects of Static Electricity." By Prof. W. J. Morton, M.D., New York.

"Electro-Medical Eccentricities." By Newman Lawrence, M.I.E.E., London, England.

"The Graphic Study of Electrical Currents in Relation to Therapeutics." By J. H. Kellogg, M.D., Battle Creek, Mich.

"The Action of the Continuous Current within the living Tissues as distinguished from the local Polar Action." By Prof. W. J. Herdman, M.D., Ann Arbor, Mich.

"The Therapeutic Application and the Theory of Alternating Currents." By Dr. Georges Gautier, Paris, France.

"The Treatment of Fibroid Tumors with Electricity." By Dr. Georges Gautier, Paris, France.

"Induction Coils." By Mr. A. E. Kennelly, of the Edison Laboratory.

"Electrolysis in Tumors of the Bladder." By Robt. Newman, M.D., New York.

"The Present Position of Electricity in the Treatment of Ectopic Gestation." By A. Brothers, M.D., New York.

"Electro-Therapeutics in Salpingitis." By W. B. Sprague, M.D., Detroit, Mich.

"Report of a Case of Ascaris cured by galvanism." By Hoffer Walker, M.D., Toronto, Canada.

"The Primary Action of the Galvanic Current on the Blood. It increases the amount of Ozone it contains, as shown by Chemical Tests of the Blood in the Arteries." By J. Mount Bleyer, M.D., and M. M. Weil, M.D., New York.

"The Conservation of Energy as a Successful Factor in Electrotherapy." By Horatio R. Bigelow, M.D., Philadelphia. "Synovitis treated by Cataphoresis." By F. H. Wallace, M.D., Boston, Mass.

"The Use of Static Electricity in the Treatment of Incipient Insanity." By W. F. Robinson, M.D., Albany, N. Y.

"Further Study of Electrical Anesthesia and Frequency of Induction Vibration." By W. F. Hutchinson, M.D., Providence, R. I.

"The Absorption of Fibroid Tumors by Mild Electric Currents." By R. J. Nunn, M.D., Savannah, Ga.

"Some Observations on the Fine Wire Coil or Current or Tension." By H. E. Hayd, M.D., Buffalo, N. Y.

"The Treatment of Subinvolution by Electricity." By C. C. Cannaday, M.D., Roanoke, Va.

"Successful Treatment by Electrolysis of four additional Cases of Esophageal Stricture with Exhibition of Two Cases." By D. S. Campbell, M.D., Detroit, Mich.

"The Treatment of Dysmenorrhea by the Galvanic Current." By A. Laphorn Smith, M.D., Montreal, Canada.

"Notes upon some Uses of Galvanism in Surgery." By W. B. D. Beaver, M.D., Reading, Pa.

Several other papers of equal interest have been promised, but the papers have not yet been received.

MARGARET A. CLEAVES, Secretary.

Pan-American Medical Congress.

WASHINGTON, D. C., August, 1893.

The Transportation Committee of the Pan-American Medical Congress, which meets in Washington, D. C., September 5th to 8th, 1893, makes the following announcement in regard to reduced rates for delegates and members of their families from all sections of the United States, also

from the Pacific Coast, Ports of Mexico and Central America:

Delegates from the territory of the Trunk Line Association east of Pittsburgh and Erie and Buffalo, will be accorded one and one-third fare for the round trip on the certificate plan.

The lines combined in this territory are as follows:

Grand Trunk Ry., N. Y. C. & H. R. Rd., West Shore Rd., D. L. & W. Rd., N. Y. O. & W. Ry., Pennsylvania Ry., Cent. Rd. of N. J. Ches. & Ohio Ry., Lehigh Valley Rd., N. Y. L. E. & W. Rd., Balt. & O. Rd., Phil. & Read. Rd.

Delegates from points in New England States in the territory of the New York and Boston Lines Passenger Associations, will be accorded one and one-third fare on the certificate plan.

Delegates from points in Central Traffic Association, embracing the territory from Buffalo, Pittsburg and Parkersburg, W. Va., in the East to Chicago and St. Louis on the West will be accorded one fare and one-third on the certificate plan.

Delegates from points in Southern Passenger Association, embracing the territory South of the Ohio river and Potomac river and East of the Mississippi river will be granted one and one-third fare on the certificate plan.

Delegates from points west of the territory of the Central Traffic Association can avail themselves of the World's Fair excursion tickets as far as Chicago and secure from Chicago the fare and a third on the certificate plan to Washington.

Delegates from South America, Pacific Coast, points of Mexico or Central America, can secure from point of starting round trip tickets to Chicago at the World's Fair rate, either by way of San Francisco or New York. The latter can secure from New York the fare and a third on the certificate plan on application to the ticket offices of either the Penn. R.R. or B. & O. R.R.

The certificates referred to must be secured at the time of the purchase of the ticket to Washington on which, properly signed by Dr. H. L. E. Johnson, Chairman of the Transportation Committee, the reduced rate will be allowed returning. To be more specific the full fare is paid on the going trip to Washington and a two-thirds reduction is allowed when the ticket is purchased in Washington for the return trip. These certificates must be obtained at the ticket offices at the time the ticket is purchased. Be sure to state that you are a delegate and will be in attendance at the meeting. Respectfully, yours,

DR. H. L. E. JOHNSON.

Chairman, Committee Transportation.

1400 L Street, N. W., Washington, D. C.

The Journal Train.

Office of

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.
CHICAGO, August 21, 1893.

To Delegates and Their Families:—

The Pan-American Medical Congress will convene in Washington, D. C., September 5.

The Pan-American train from Chicago and the northwest, run under the auspices of the Journal, will leave Chicago, 8:30 A.M., Sunday, September 3, via Big Four from Central Station, 12th Street and Park Row. The train will consist of palace sleeping cars, and run through without change via the popular Big Four and the picturesque Chesapeake & Ohio railways, passing through Indianapolis, where the Indianapolis, Peoria and St. Louis delegations will join the train, and at Cincinnati that delegation will also join the train.

Excursion Rates.—A rate of one and one-third fare on the certificate plan has been authorized. Any person attending the Congress can get this rate. Buy a first-class limited ticket to Washington, and take a certificate from ticket agent at starting point, stating you have paid first-class fare going, and when properly signed by the Secretary of the Congress it will entitle you to one-third fare returning.

Persons going via Chicago should buy excursion tickets to Chicago and purchase Washington tickets there.

Be sure that your ticket reads, via the Big Four and the Chesapeake & Ohio Railway, Chicago office, 234 Clark street. Rates always as low as via any other route. Leave Chicago, Big Four railway, 8:30 A.M.; leave Indianapolis,

Long Traction Hip Splint, with Proper Method of Applying & Extension," by Henry Long Taylor, New York City. "Improved Apparatus for Paralysis Disease," by Henry Long Taylor, New York City. SECTION ON HYGIENE, CLIMATOLOGY AND DEMOGRAPHY

PRELIMINARY NOTICE.—The Headquarters of this Section will be at the Hotel Richmond, corner of 17th and H streets, N. W., the property of which, Major F. W. Coleman, has kindly offered, reduced rates for the use of this Section. The Section will be delivered on Tuesday, Sept. 6, at 4.30 P. M., at the place which shall be assigned by the committee on halls. Regular sessions will be held on Wednesday and Thursday, Sept. 6 and 7, from 10 A. M. to 1 P. M. and from 3 to 5 P. M., and a final session on Friday, Sept. 8, from 10 A. M. to 1 P. M. The Director in charge of the U. S. Naval Museum of Hygiene, that building will be open for inspection by members of the Congress from 9 A. M. to 1 P. M. daily, on Wednesday, Thursday and Friday, Sept. 6, 7 and 8. THOMAS.

"America in Philosophy"—Past, Present, and Future, by Isaac Ott, Executive President of Section, Eastern P., *Philosophy of Nature*, by Joseph B. S., New Orleans, La., "The Effects of Lesions of Certain Parts of the Brain upon the Motor Processes," A. E. T. Beebe, Jr., Philadelphia, Pa., "The Mechanism of the Reflexes," G. B. B. B. B., Italy, "The Glomerular Action of Iodine," W. S. Carter, Philadelphia, Pa., "On the Absorption of Iron in the Animal Body," A. B. MacCall, Jr.,

MISCELLANY.

He reads the Journal.—The editor of the *Pittsburgh Medical Review* reads the JOURNAL carefully, and a recent number of that valuable periodical points out a typographical error that escaped the eye of the proof reader of the JOURNAL some numbers back. He does well when he reads the JOURNAL. People are always improved by reading carefully the excellent original papers exclusively furnished the JOURNAL. The medical news, always fresh, crisp and sparkling as it appears in the JOURNAL, refreshes the reader like a mid-summer draught from a cool natural fountain, and even advertisements when they appear in the JOURNAL have an added charm and an interest to members of the Association which they can not take in advertisements when they appear elsewhere.

Sir B. W. Richardson.—Dr. Richardson, the well known sanitarian and editor of *Ischpamid*, has been knighted by the Queen of England, among those receiving "birthday honors." Dr. Charles Cameron has been made a baronet on the same occasion.

Local Anaesthesia from Aristol.—Several observers have called attention to the soothing effects of aristol when applied to painful exposed surfaces. This has been especially noted when aristol has been employed as a dressing for burns, bed-sores, and blisters, or for irritating ulcers. At the same time, the analgesic action of aristol does not interfere with the strong healing power necessary to a prompt cicatrization of denuded areas, while it seems to favor the growth of normal granulating surfaces. It is not easy to say just how far the power of aristol as a local anaesthesia may be made useful in the operation of minor surgery, but some recent experiments point to a probable new field of usefulness for this remedy in the direction cited. The following paragraph from the *Kansas Medical Journal* is quite significant as showing that the advantages of aristol as an analgesic have not passed unobserved: Dr. S. M. Riggs has made some interesting experiments in the use of aristol as a local anesthetic. A hypodermic injection of a solution in glycerine was made on a kitten with the result of complete local anaesthesia. The animal made no resistance to a cutting operation and was apparently unaware of being injured. The advantages of using as a local anesthetic the same drug which was afterward to be applied to the operation wound as a cicatrizing would of course, be very important.

The William F. Jenks Memorial Prize.—The third triennial prize of five hundred dollars, under the deed of trust of Mrs. William F. Jenks, will be awarded to the author of the best essay on "Infant Mortality during Labor, and its Prevention." The conditions annexed by the founder of this prize, that the "prize or award must always be for some subject connected with Obstetrics, or the Diseases of Women, or the Diseases of Children," and that "the Trustees, under this deed for the time being, can, in their discretion, publish the successful essay, or any paper written upon any subject for which they may offer a reward, provided the income in their hands may, in their judgment, be sufficient for that purpose, and the essay or paper be considered by them worthy of publication. If published, the distribution of said essay shall be entirely under the control of said Trustees. In case they do not publish the said essay or paper, it shall be the property of the College of Physicians of Philadelphia."

The prize is open for competition to the whole world, but the essay must be the production of a single person.

The essay, which must be written in the English language, or if in a foreign language must be accompanied by an English translation, should be sent to the College of Physicians of Philadelphia, Pennsylvania, U. S. A., before January 1, 1896, addressed to Horace V. Evans, M.D., Chairman of the William F. Jenks Prize Committee.

Each essay must be typewritten, distinguished by a motto, and accompanied by a sealed envelope bearing the same motto and containing the name and address of the

writer. No envelope will be opened except that which accompanies the successful essay.

The Committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year.

The Committee reserves the right not to make an award if no essay submitted is considered worthy of the prize.

College of Physicians of Philadelphia, N. E. corner Thirtieth and Locust streets, James V. Ingham, Secretary of the Trustees.

Eleventh International Medical Congress.—In consequence of the sanitary condition of several of the European States, which prevents their medical men leaving home, and following the advice of many of the most prominent scientists, both Italian and foreign, the executive committee of the above Congress has decided, by a large majority, to postpone the meeting till April, 1897.

The exact date of the inauguration will soon be fixed.

THE PUBLIC SERVICES.

Naval Delegates.

Secretary Herlieth has detailed Medical Director A. J. Gorgas, Surgeon C. A. Siegfried, Surgeon H. G. Berger, and Passed Asst. Surgeon D. M. Gultenas representatives of the Navy Department at the Pan-American Medical Congress which is to meet in Washington, D. C.

Army Delegates.

Special orders from the Adjutant General's Office, Washington, D. C., dated August 18, detail four officers to represent the Medical Department of the Army at the Congress. They are Colonel Bernard J. D. Irwin, assistant Surgeon General; Lieutenant Colonel Dallas Bache, deputy Surgeon General; Major David L. Huntington, Surgeon, and Major Charles Smart, Surgeon.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from August 12, 1895, to August 18, 1895.

Lieut. Col. JOHN H. JASPER, deputy Surgeon General, retirement from active service August 12, 1895, by operation of law, under the provisions of the Act of Congress approved June 30, 1892, is announced. By direction of the President.

First Lieut. HABELAN, E. McVAY, Asst. Surgeon (San Carlos, A. T.), is granted leave of absence for one month, to take effect when relieved by another medical officer, with permission to apply for an extension of fifteen days.

Major HENRY R. PHELPS, Surgeon U. S. A., is granted two months' leave of absence, when relieved from duty at Fort Wayne, Mich.

First Lieut. JAMES D. GLENNAN, Asst. Surgeon U. S. A., is granted leave of absence for twenty days, to take effect upon the conclusion of his examination for promotion.

Navy Changes. Official list of changes in the Medical Corps of the U. S. Navy, for the week ending August 19, 1895.

Surgeon A. M. MOORE and P. A. Surgeon C. W. RUSH, placed on retired list.

Asst. Surgeon R. M. KENNEDY, promoted to P. A. Surgeon.

Medical Director J. H. CLARK, Medical Inspector C. H. WHITE and Surgeon J. L. NELSON, ordered as members medical examining board.

P. A. Surgeon M. F. GATES, from Naval Hospital, Portsmouth, and recorder naval medical examining board, September next.

P. A. Surgeon A. R. WESTWORTH, ordered to Naval Hospital, Portsmouth, N. H.

Medical Director A. C. GORGAS, Surgeons C. A. SIEGFRIED and H. H. BERGER, ordered as delegates to Pan-American Medical Congress.

Surgeons B. S. MCKIE and L. G. HENSENBERGER, to Naval Academy to examine applicants for admission to Naval Academy.

No. 10.

ORIGINAL ARTICLES.

LACTATIONAL INSANITY.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY GEORGE H. ROHE, M.D.

SUPERINTENDENT OF THE MARYLAND HOSPITAL FOR THE INSANE; PROFESSOR OF THERAPEUTICS, HYGIENE AND MENTAL DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE, MD.

Nearly all writers upon insanity describe the mental derangements occurring during pregnancy, the puerperium, and the nursing period under the collective title "puerperal insanity." Careful observation will, however, show certain points of distinction which may be noted, both in the symptomatology as well as in the causative factors of these mental disturbances.

Those authors who classify puerperal insanity into the insanity of pregnancy, of the puerperal period proper, and of the lactational or nursing period, arbitrarily assume that the latter begins six weeks or two months after labor. In a general way this limitation though arbitrary may be accepted, for obstetric authors count as belonging to the puerperium that period of time occupied by the involution of the parturient organs which is usually stated to be six weeks.

Prolonged or excessive lactation is given as the chief cause of insanity occurring during the nursing period. In most cases this is probably true, yet there are some cases in which the disease must be attributed to other etiological factors.

Recent careful study of insanity during the lying-in period has shown its frequent dependence upon septic puerperal processes. Certain observations of my own presented to this Section at the last annual meeting may, I think be regarded as confirmatory of this view. In studying the causes of insanity during the period of lactation, however, not sufficient discrimination has hitherto been exercised by writers upon the subject, although Gooch as early as 1829 called attention to the necessity of such discrimination.

Even in cases where the psychical symptoms of the attack are carefully recorded too little attention has been paid in my opinion to the bodily condition. Of course such marked characteristics as anemia or unusual emaciation could not fail to be noted by the most superficial observers, but the cases where a careful and thorough examination of the condition of the bodily organs has been made are rare. In insanity the psychical phenomena are generally so striking as to overshadow bodily anomalies and thus these fail of notice.

Among the most recent authorities, however, Dr. Bevan Lewis regards the exhaustion and sequelæ of labor, and defective uterine involution as important

etiological factors, especially in the earlier cases of lactational insanity. Levisstein-Schlegel also, lays stress upon local diseases and displacements of the pelvic organs as causes. "It appears," says this author, "that the local (pelvic) irritations acting upon the central organ (brain) are active, both as determining the duration as well as the course of the mental disorder."

The following cases of insanity beginning during the nursing period have been admitted to the Maryland Hospital for the Insane in the last two years.

They form 7.4 per cent. of the total number of women admitted during this period. The cases may be classed clinically as melancholia two, mania one, and confusional insanity two. Of the latter, one died and the other progressed to profound consecutive dementia. The case of mania was discharged after six months' treatment practically recovered. One case of melancholia was discharged recovered after repairing a badly lacerated cervix uteri; the other case is still under treatment though much improved.

Case 1.—A. H., a well developed Jewess, 27 years of age; been married three years and is the mother of two children, the youngest being five months old. There is no family history of insanity. The patient's parents are sober and industrious. She has not used alcohol or opium. About ten years ago she had an attack apparently of a hysterical nature from which she recovered completely.

About five months previous to admission she gave birth to a child. The labor is reported to have been normal in all respects. Four months afterward she had an inflammation and abscess of one breast and immediately following it a change in her mental state was noticed. She would talk to herself and imaginary people. She lost interest in her home occupations and in her children. These symptoms increased. She became noisy, talkative, restless, running about the house and screaming at the top of her voice. When spoken to she paid no attention. Her husband and friends lost all control of her. Her language became exceedingly vulgar, profane and obscene. She was always trying to divest herself of her clothing. There were evidently hallucinations of hearing.

On November 2, 1891, she was admitted to the hospital. The symptoms mentioned above were present. In addition her appetite was very poor, she was restless, running up and down the ward, screaming, laughing and crying at intervals, constantly unbuttoning her clothing, disarranging the things in her room and soiling her bedding and clothing. She slept badly and kept her roommate awake most of the time.

A note dated November 21, 1891, says: "She is still restless, talkative night and day, refuses to eat until threatened with forcible feeding, wants constantly to undress herself, very untidy, annoys her roommate at night, soils her bed and room."

This condition continued until December 30, when she became much more composed, less talkative, and more cleanly. She also showed interest in her surroundings and in the visits of her friends.

Her improvement continued from this time and on May 22, 1892, she was discharged well. At this date May 20, 1893, she remains well.

Case 2.—Mrs. M. B., a cultivated white woman of American descent, 49 years of age. She has had five children. Her disposition was always cheerful before she was taken with her mental trouble. Hereditary taint was denied, but

her father was intemperate. Her first attack of mental derangement, melancholic in character, came on four months after the birth of her youngest child. From this attack she recovered in four months. Four years later she had a similar attack from which she recovered in six months.

The present attack began suddenly three weeks before admission. She had simple melancholia, was low spirited, cried, lost interest in her daily pursuits and had delusions of having committed the unpardonable sin. She had no suicidal tendencies. On admission September 10, 1892, no hallucinations were discoverable. She took no interest in her surroundings, desired to be alone and avoided the other patients. She was often found in her room crying. She would not volunteer any remark, but when pressed would manifest the old delusion of having forfeited the mercy of Providence.

This patient is still in the hospital, but has greatly improved since her admission. She is more lively, at times quite cheerful, takes interest in the happenings about the house and the welfare of the other patients, walks out in the garden on pleasant days, and if no relapse occurs will soon be able to return to her home and family.

Case 3.—Mrs. F. W., a white woman 38 years of age, married eleven years and mother of five children. Distinct hereditary history of insanity. Her last child was born in March, 1890. Four months afterward she showed the first symptoms of mental derangement. Previously she had always been neat, industrious and cheerful. No history of the habitual use of opium or alcohol could be obtained. About a week preceding the outbreak she complained of a peculiar sensation in her head and very profuse menstrual flow. The attack came on suddenly with delirium followed in a few days by mania. She fought, swore, talked incessantly, was restless and unable to sleep. Her conversation was incoherent and disconnected. She twice attempted suicide, once by jumping from a window and the second time by hanging. She was committed to an asylum where she remained two years and thence transferred to this hospital on October 22, 1892.

When received she was in a condition of advanced dementia. She is apathetic, listless, refuses to talk, is dirty in her habits, soiling her clothing and bedding constantly. Saliva is always dribbling from her mouth and adds to the repulsiveness of her expression. She requires constant urging to take her food. Sleep is good. Her physical condition is bad. A vaginal examination a short time after admission revealed a bad laceration of the cervix but no appreciable abnormalities of the uterus or ovaries.

At the date of writing she has passed into deeper dementia.

It would be hazardous to express the opinion that attention to the laceration of the cervix at the proper time might have stayed the progress of the mental alienation; but shall the neglect of the physician who for two years saw this patient every day, who was or should have been familiar with her history and who failed to inform himself of her bodily condition by a thorough examination, be passed over in silence? Did he do his whole duty by this woman?

Case 4.—Mrs. I. H., a white woman of English birth, 32 years of age, and the mother of three children. She has been married ten years. No history of insanity in the family. Her disposition was cheerful; she was industrious and exceptionally neat in her household. She was not addicted to the use of opium or alcohol. Her labors had all been normal, and the menstrual flow had always been regular and normal. Since the birth of her last child her physical health had gradually failed. Six months after the last labor she began to get careless about her house; her disposition changed. She became talkative, irritable, forgetful, indifferent to the condition of her children. She would gad about among the neighbors, and accuse them of spreading stories about her. All this time she continued to nurse her child, and when admitted to the hospital, eleven months after the birth of the child, her breasts were very tumid.

She was brought to the hospital March 2, 1892, a typical case of confusional insanity. She was very much emaciated and anemic. She was incessantly talking in the most confused and incoherent manner. Occasionally the delusion was apparent that she fancied her neighbors talking about her, but her attention could not be concentrated upon any subject. Her condition was more nearly that of acute delirium than of mania. She had no appetite and slept only after the administration of hypnotics. She soiled her clothing and bed.

Her physical condition which was bad at the time of ad-

mission did not improve. Her tongue became very dry, her pulse rapid and weak, and in spite of stimulating and nourishing diet and rest in bed she grew weaker and died on March 20, eighteen days after admission.

The pelvic organs in this case were normal. The history points to the exhaustion of the nursing as the cause of the mental aberration. Earlier stimulation with removal of the source of exhaustion might have saved her life.

Case 5.—Mrs. L. B., aged 28 years, white, was married eighteen months before admission. Three months after her marriage she had a child the paternity of which was admitted by her husband. No history of insanity in her family. Five months after her labor she began to grow depressed and troubled about her disgrace. She became listless and careless in her household duties, would often be found crying, was restless and twice attempted suicide. She was admitted to the hospital on December 9th, 1892, with simple melancholia. She has no delusions. Her conversation is rational and connected, but she is very much depressed. She begs to be allowed to go home or to die. At intervals she brightens up somewhat but again becomes depressed. Her nutrition is fairly good, temperature normal, pulse eighty and regular, tongue slightly coated, urine normal in quantity and composition.

Vaginal examination revealed a ruptured perineum, and a deeply lacerated cervix, the tear on the left side extending nearly to the vaginal junction. The right ovary was tender and probably adherent.

One month after admission her improvement not having been very marked, the cervix was stitched up with silk-worm gut. The improvement was notable from the day of the operation. The patient became cheerful, happy, interested in the work about the ward, and was discharged completely recovered three weeks later. At the present writing she continues well.

It will be observed that there is nothing distinctive in the symptomatology of these cases; nothing except the outbreak during the nursing period, by which they could be recognized as "lactational insanity." Hence the term, "lactational insanity" in no way designates an especial form of insanity.

Gooch, with the clearness of the accurate clinical observer says: "If a physician was taken into the chamber of a patient whose mind had become disordered from lying-in or nursing he could not tell by the mere condition of her mind that the disease had originated in these causes." Stress is laid upon this fact because the question is often asked whether puerperal and lactational insanity do not have characteristic symptoms.

The prevailing impression is that the preponderating proportion of these cases are cases of mental depression or melancholia, but this is not borne out by statistics. The cases of mania and melancholia are nearly equal.

The average proportion of puerperal insanity in its widest sense to all insanities in women is about 10 per cent. Among these the cases of lactational insanity number on an average 35 per cent. This is based on a total of 1,053 cases of puerperal insanity from various authorities, of which 371 were lactational.

The practical question of prognosis is difficult to settle by aggregate statistics. Clouston reports thirty-one out of forty recovered and three more discharged much improved, the percentage of actual recoveries being 77.5 per cent. One in forty died. Lewis reports 65.6 per cent. recoveries and 12 per cent. deaths. Ripping had 42.5 per cent recoveries and 5 per cent deaths, and Schmidt (Berlin Thesis, 1880) only 28.8 per cent recoveries and 6.3 per cent of deaths. Without further details these widely discrepant results are difficult of explanation.

Gooch, writing at a time when most physicians regarded insanity as merely a disorder of the mind unconnected with physical processes, states the

problem of treating mental disease with a force and clearness not exceeded by any modern writer. He says: "We have no power by medicinal agents of relieving a disordered mind, *excepting indirectly through the disorder of the body with which it is connected*. It is therefore impossible to stir one step in the treatment of the disease without first ascertaining what this disorder is, or, if different in different cases what they are, how to discriminate them and whether experience shows that one is more common than the other." Bevan Lewis, writing from the standpoint of the alienist, says: "In most instances our patient's bodily condition claims the chief attention." The indication for treatment is therefore primarily the bodily condition, and this can be ascertained only from a careful physical examination and not from a study of the psychical manifestations. If the examination shows profound anemia, loss of appetite, etc., it is incumbent on the physician to inquire closely into the functions of the digestive, circulatory, respiratory and pelvic organs, the condition of the breasts, the existence of local sources of irritation or exhaustion in the chest, the abdomen or the pelvis. Physical abnormalities to which the mental disturbance is traceable will not always be discovered, but when found will render the treatment more rational and its results more certain.

The treatment of lactational insanity resolves itself simply into the exercise of the general principles of therapeutics. Remove sources of irritation, correct aberrant functions, restore wasted strength. These principles if consistently carried out will usually lead to success.

THE ESSENTIALS OF SUCCESS IN VAGINAL HYSTERECTOMY.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY HENRY T. BYFORD, M.D.

Professor of Gynecology in the College of Physicians and Surgeons of Chicago; Professor of Clinical Gynecology in the Woman's Medical College of Chicago; Professor of Gynecology in the Post-graduate Medical School; Gynecologist to St. Luke's Hospital; Surgeon to the Woman's Hospital, etc.

The experience of gynecologists is gradually establishing the fact that the removal of the uterus through the vagina is not in itself a very dangerous operation. Of course there is a mortality connected with all operations involving any considerable amount of cutting, but there is nothing about the one under consideration involving any special, unavoidable danger. What there is comes not so much from the danger of the operation as from certain avoidable circumstances which may be considered under three heads, viz: 1. Unsuitable cases for operations; 2. Imperfection in the technique; 3. Mistakes in the after-treatment.

It would be absurd to maintain that unfavorable circumstances can always be avoided in practice, yet there is much to be accomplished in that direction, and a great majority of the deaths due to the operation ought not to occur.

1. *Unsuitable Cases for Operation.*—Unfortunately, the great majority of cases are unsuitable ones—they are usually neglected cases of malignant disease that come to us too late. Sometimes the patient does not apply soon enough for treatment; at other times the physician does not promptly recognize the nature of the trouble. The parts about the uterus are infected, the patient has septicemia, is anemic, or perhaps has some kidney or heart complication;

or she may be too old, and yet pleads to be given her only chance for recovery.

It is our duty to examine carefully as to these conditions and select our cases more carefully. In the majority that come up for operation the malignant disease has so far advanced that we are quite certain that it will return, and in that case we should not operate except under the most favorable circumstances, lest we hasten death. Yet such is done every day. When there is great probability of a cure by operation, there is seldom septicemia nor profound anemia; and any kidney or heart trouble can be rendered much less harmful by preparatory treatment, and thus favorable conditions be obtained. A large proportion of the present mortality will be obviated when it comes to be recognized by the general practitioner that hysterectomy is for the early or simple cases instead of those already far advanced. Cases are being constantly sent to the gynecologist for a hysterectomy in which the entire pelvic cavity is infiltrated, and the medical attendant, after dilly-dallying until the fatal die is cast, finally announces that the only hope of a cure lies in a hysterectomy.

2. *Imperfection in the Technique, and (3) Mistakes in the After-treatment.*—Given a proper case for hysterectomy, a fatal result is due almost always to errors in the technique. So many methods have been described, and so many different maneuvers recommended that the beginner is almost necessarily at sea and is sure to employ some plausible but disastrous modifications and innovations, with a result that adds immensely to his unenviable experience. I have found that it is not the particular method employed that influences the results, except in one way, viz: in employing methods and maneuvers to suit the particular case.

I have used ligatures exclusively twenty-four times with one death; the forceps exclusively in nine cases with no death; both forceps and ligatures on the stumps in seven cases with no death; forceps to stumps and catgut to vagina and connective tissue in four cases with no death; and ligatures to stumps and forceps to vagina and connective tissue in one case with recovery. I have usually separated the bladder before making my posterior incision, but sometimes have opened the peritoneal cavity behind first. I have usually ligated or clamped from below up, but have sometimes retroverted the uterus and put on forceps from the peritoneal end of the broad ligament. I have a few times cut away portions of the cervical end of the uterus, other times I have bisected the organ. I have sometimes ligatured the vagina the first thing, at other times the last thing—at other times put forceps to its edges, and at other times have let it alone. The great thing is to see what is to be done and no more, and to do the thing required and only that.

First of all we must secure against hemorrhage. When the vagina is of fair size and the cervix can be pulled down, ligatures are best because we can take a proper amount of tissue, tie it firmly and safely, and have nothing in the way to prevent us from tying the next section of the broad ligament securely, and finally have plenty of free room for ligaturing or pinching arteries in the vagina or connective tissue, or of sewing up the edges. Many a woman, however, has lost her life because the surgeon could not or else did not take time or pains to tie securely. Yet he ought always to feel when he is

through that the patient is not in the least danger of bleeding to death. Forceps are less desirable, because after the first one is put on it is in the way and hampers all subsequent maneuvers, because he can not always be sure that some tissue may not slip out of them, or that some old instrument, or some untried one, may not bend, break, unclasp, cut the tissue or press injuriously upon some viscus. An abundance of tissue should always be left on the uterine side of the forceps to prevent slipping, for it will all slough off at the blades, and the operation be just as thorough as if we did not leave so much tissue.

In case, however, the vagina be narrow, or the cervix can not be pulled down, or the connective tissue be too greatly thickened and altered by old inflammatory action, the surgeon should not employ the ligature, because he can not be sure of tying tightly and securely. He should then ligature such tissue about the cervix as he can ligature well, and put forceps on the rest, or should use forceps exclusively. He can usually place a forceps as far as the finger can reach, or he can place a forceps on the base of either broad ligament, cut off the intervening part of the uterus, pull the rest down a little, and place forceps higher up, cut away some more and so on (*morcelement*). It is a great mistake to attempt to include too much tissue in one pair of forceps. If we include the whole of the broad ligament the base, being thicker, will be well compressed, while the thinner upper portion may slip out and bleed. It is better to put a pair on the cervical portion or base and another on the upper portion on either side. There is a tendency to use forceps too long and slim. They should be short and thick that they may not spring at the end, or project too far out of the vulva and strike the pillow placed under the patient's knees. There are large arteries in the sacro-uterine ligaments that are sometimes not included in the first row of ligatures or clamps. These should always be sought for before the operation is finished. In seeking for these bleeding vessels without knowing where to seek them, it has happened that the upper ligatures or forceps have been loosened by rough handling.

The next thing to do is to take the proper care of the peritoneum. Imperfection of technique in this respect is the cause of the many deaths from peritonitis, ileus and septicemia that have occurred. While ligaturing requires the most operative skill, the management of the peritoneum requires the greatest judgment. If the intestines have been properly prepared by purging, dieting and intestinal antiseptics, there will be but little trouble in avoiding interference with them during the removal of the uterus. When the uterus is taken away there is a gap in the peritoneal cavity between the stumps, into which a knuckle of intestine is apt to fall. It is the management of this intestine and the gap under it that requires the use of sound judgment, for the advice given by different operators as found in the literature is contradictory.

In the first place we must remember that the stumps will slough, or at least the ligatures will become infected. Hence, one great problem is to prevent infection of the peritoneal cavity and septic peritonitis. To do this we must remove all debris from the pelvic peritoneal cavity, first with the sponge and, if we have operated upon a septic uterus, next by washing it out with a stream of sterilized

water. If we leave debris there infection will follow as surely as the night will follow the day, for inside of forty-eight hours the contiguous stumps will stink. Having cleaned the pelvis we must prevent the adhesion of an intestine between the stumps with its accompanying danger of ileus and septic peritonitis. There are several means of doing this. The first and most important is to draw forward the omentum if, as is often the case, it has not presented itself, and place it under the intestine so as to contract the adhesions with the stump or peritoneal edges and thus leave the intestine free. If we have used ligatures on the stumps we can draw the stumps together, not pulling on the ligatures, below the omentum and sew them together, thus fixing them extraperitoneally. If practicable it adds to the safety of the patient to catch the anterior and posterior cut edges of the peritoneum and stitch them to their respective anterior and posterior vaginal edges and thus close the raw connective tissue surface, or stitch them to the united stumps, leaving an opening on either side to drain the peritoneal side of the stumps. If we have used forceps we can not approximate the stumps accurately, but can put the omentum between their upper ends. Nor can we sew the peritoneal edges to the vaginal edges. In fact, the presence of the forceps prevents us from doing any satisfactory sewing. We will have to depend upon the shielding omentum or upon a gauze tampon to hold up the intestines. And it is just here that a serious mistake is many times made; and that is to place the tampon high up among the intestines in order to hold them away from the stumps and drain the peritoneal cavity. Those who do thus forget two things, viz: that the peritoneal cavity above does not want draining but merely wants to be let alone, and that the gauze that drains the peritoneal cavity will irritate it and infect it, because infection exists in the contiguous necrotic or ulcerating stumps. The conditions would be different could we depend upon keeping the stumps aseptic. Besides, when we remove the gauze we have a foul cavity whose walls are partly formed of intestines. There is also danger of paralysis of the adherent intestines with serious results, or of ileus from a kink of compressed and adherent intestine. I believe that the vagina should always be tamponed with iodoform gauze, but in case the peritoneum can not be shut off above, the tampon should be against omentum above, and should only be put high enough to drain the stumps, and never project above them. In case there be raw tissue in the pelvic peritoneal cavity the gauze may project only far enough backward to drain these, and should be against the very bottom of the pelvic cavity and not project upwards. The less gauze that extends beyond the peritoneal edges, providing it drains the raw surfaces, the better. Drain adequately what needs drainage, but do not drain a bit more. When the gauze is removed it will usually be necessary to douche the vagina with antiseptic solutions. If the gauze has reached the intestines there will be danger of the solution breaking through the adhesions into the peritoneal cavity, as I have known to occur in two instances, happily not in my own cases, with fatal results. The adhesions, although firm in character, are sometimes not extensive enough to stand the pressure. If the gauze has not been placed too high it can remain from four to five days without causing irritation or any rise in temperature. I find that I have less temperature by

leaving the tampon for at least four days. The douche should not be given until six or eight hours after the gauze has been removed, in order to give the parts to contract, and there should be a return douche, given without force and with a return tube placed beside the syringe point. After that, antiseptic solutions should be used every six or twelve hours without the return tube. The patient should, if possible, be kept on her back for eight or ten hours or until the omentum has become adherent over the peritoneal opening or wound.

All of these particulars may not seem important, but if carried out will be followed by a recovery without tympanitis, without abdominal tenderness, without high temperature and, I am almost tempted to say, without danger.

I have adhered to them in thirty-seven cases, being careful to omit no detail that would add only a little to the security of the patient, and have had the good fortune to lose only one patient from the operation, although I am sorry to say that, owing to the advanced stage of disease, a large proportion of the cases of malignant disease of the cervix have died later of a recurrence. Nearly all cases of malignant disease of the uterine cavity have remained well.

To recapitulate:

1. Operate only on cases in which we can operate in healthy tissue.
2. Use the method and maneuvers adapted to each individual case—not adhering rigidly to any one for all cases.
3. Ligature enables us to do a more complete operation than forceps, but forceps should be used when ligatures can not be applied with accuracy.
4. When possible, place omentum between the intestines and the stumps.
5. Draw the ligatured stumps together, and attach the peritoneal edges either to the vaginal edges or to each other.
6. Pack iodoform between the blades of the forceps, but do not allow the packing to project upward between the intestines.
7. Leave the packing for four days as a rule.
8. Begin douches about eight hours after the packing is removed and use a return tube the first time.
9. Keep the patient on the back for forty-eight hours.

VENTRAL HERNIA FOLLOWING LAPAROTOMY—ITS CAUSE AND MEANS OF PREVENTION.

BY HENRY O. MARCY, M.D.
BOSTON.

Although we live in the era which is denominated revolutionary in the science and art of surgery, he who proposes modifications to long-established rules should do so only after the most convincing evidence upon his part of their manifest advantage and importance. It is in this spirit that I ask the judicial consideration of my surgical friends to the following brief communication:

Laparotomy, from a great variety of causes, is now becoming so frequent that any method of improvement in its technique or results becomes of much greater importance than formerly. The attention of surgeons to the more essential factors of the opera-

tive procedures within the abdomen has very naturally caused the peritoneum to assume more consideration, and as it often treated by even practiced surgeons, seems to be looked upon as a trivial matter. However, it is estimated that about 10 per cent. of all laparotomies result in ventral hernia and in order to lessen or prevent this it is quite the standard rule to apply a strong abdominal support to be worn for months. Only within a few days I have seen a patient with a painful ventral hernia upon whom laparotomy for the removal of the uterine appendages was performed in the largest hospital in New England about eight months ago. The incision scarcely exceeded three inches, and immediately upon recovery the patient was fitted with an abdominal supporter with bars like drawers to prevent the slipping of the bandage and this had been kept tightly laced even to the floating ribs, in her instance a most uncomfortable and valueless support. With our present results there is a demand to revise, and improve if possible, the methods of operation. The importance of including the peritoneum within the sutures was early shown by Sir Spencer Wells and he advised the approximation of the divided edges of the wound with the utmost care.

During the last eight years I have employed exclusively the buried tendon sutures in the closure of all abdominal wounds, except for a few months, during which time catgut was substituted for tendon, because of the difficulty I had in obtaining a supply of tendon from Australia. For more than ten years preceding this, I had used the buried animal suture in a great variety of wounds, and was led to its adoption in laparotomy because of its exceptional value in the reinforcement of the weakened structures, especially as demonstrated in operations for the cure of hernia. My method from the first has been essentially the same. The peritoneum closed separately; this may be effected by suturing in a variety of ways. For ease and rapidity, if for no other reason, the *oblique* suture is to be preferred. I employ usually the double continuous tendon suture which is easily and rapidly taken by the use of a needle with the eye near the point, and which by re-threading with the opposite end, permits the introduction of the suture from either side through the same puncture. The result is an even, continuous and close apposition of the serous surfaces of the peritoneum, retained at rest without undue constriction. A fine tendon should be selected for this purpose. When one of the recti has been incised, as is usually the case, it is better to rejoin the muscle by a row of sutures. This finished, I consider the accurate coaptation of the thick investing fascia (*linea alba*) of the first importance. This is preferably effected by a line of sutures taken in a similar manner to the one closing the peritoneum. The more or less thick layer of fatty tissue is preferably brought into apposition by one or two light lines of running sutures, usually taken with a medium-sized, full curved Hagedorn needle, introduced from side to side deeply through the uninjured structures. Care is taken that the introduction of the needle commences exactly opposite the emergence of the preceding stitch, the importance of which is twofold. First, that the coaptation of the edges of the wound may be accurately effected; and secondly, if not less important, that the suture itself may cross at right angles to the divided tissues, so that when drawn

upon, it accurately coapts the lips of the wound and is not interposed between the injured parts. The skin is united by the use of a fine full curved Hagedorn needle introducing the stitches in precisely the same manner as just described. I have called this the *parallel suture* because each stitch is taken through the deep layer of the skin only, and is inserted exactly parallel to the line of the division of the skin, and the wound closed by collodion seal, and if each stitch is taken, entering directly opposite the emergence of the one preceding, it will be noted that when the suture is drawn upon the coaptation is accurate without puckering, and that it crosses the wound exactly at right angles to it. When a suture is introduced in this way, with precision and care, the divided edges of the skin are brought in contact with an accuracy impossible to secure by any other method, and yet the suture is completely buried. A layer of collodion, reinforced with a few fibers of cotton applied to the well dried skin completes the dressing. If the operation has been conducted with aseptic care, the wound must remain aseptic. In most instances it is immaterial whether a bandage and pad be applied, although after the removal of large tumors the support of the relaxed abdominal walls is usually a comfort.

In quite three hundred laparotomies, where a complete closure of the wound has been thus effected, I recall but two cases of ventral hernia following the operation. In one the most pronounced, the incision was necessarily a long one where I removed a large uterine myoma, but the hernia was attributable far less to the length of the wound than to the extreme thinness of the abdominal wall, which had become atrophied in an extraordinary degree because of the projection of the tumor, which had the appearance of having taken "deck passage."

In the second, there is a small opening through the fascia, very probably caused by separation and non-union of its edges.

Undoubtedly one of the most common causes of hernia is the routine use of drainage tubes, by which a portion of the wound is necessarily kept open, so that primary union cannot take place, and a portion of the wound heals by granulation. Although I have never refused operation, whenever I have felt the patient's condition demanded, I find the use of the drainage tube in my practice has scarcely exceeded 3 per cent. A second and common cause of ventral hernia is the imperfect coaptation of the parts by the use of the interrupted suture; even when taken with the utmost care, they constrict the tissues at intervals and are usually tied very tightly, in order to prevent bagging or separation of the abdominal wall between the sutures. This necessarily narrows, perhaps even to a third, the thickness of the coaptated structures, and if any of the enclosed tissues are separated, it is necessarily that portion midway between the loops of the stitches; the thickened, reinforced connecting tissue fascia (linea alba) upon the integrity of which the parietes depend in the resistance of intra-abdominal pressure. The importance of thus closing the abdominal incision appears sufficient to warrant emphasis to be made upon it, since the results of other operators, as well as my own experience, confirm the exceptional value of this procedure.

The suture, itself aseptic, aseptically buried, in aseptic wounds, marks one of the greatest advances in modern surgery, and he who is master of the

technique of its application has acquired a distinctive accomplishment of inestimable value and importance. Somewhat recently I examined the history of about six hundred operative cases thus treated in my private hospital with the result of less than 2 per cent. of suppurative wounds.

DR. JOSEPH EASTMAN of Indianapolis, said an aseptic wound with an aseptic suture, closed in the manner in which Dr. Marey had repeatedly described it, marked one of the most important eras in modern surgery.

DR. M. B. WARD of Topeka, Kan., was pleased with kangaroo tendon, and had seen it used by Dr. Marey. He thought that 10 per cent. of hernias following abdominal section was an erroneous estimate. He had only had two cases of ventral hernia in his practice. One was in the person of a fleshy lady whose weight was 196 pounds, who went home three weeks after operation. He is unusually painstaking in closing the abdominal incision.

DR. WILLIAM H. HUMISTON of Cleveland, Ohio, had had but two cases of hernia in his practice following his operation, and since adopting three rows of sutures he has had none. He got this method from Billroth's clinic.

DR. HENRY T. BYFORD of Chicago, had seen a good many cases of hernia following operations, but was quite sure they did not come from the suture material used in closing the abdominal incision. He thinks it makes no difference what material is used so long as the parts are brought together properly. If they are not properly coaptated they will not remain united, and hernia follows. An objection to the buried animal suture is that it becomes absorbed at the end of from two to four weeks, if not properly prepared, and the parts may suppurate before they become very strong.

DR. LEWIS SCHOLLER of Des Moines, Iowa, agreed with Dr. Byford that it matters little as to the material used in closing the abdominal incision. He thought the interposition of peritoneum or fat between the united parts was the chief cause of hernia.

DR. A. H. CORDIER of Kansas City, Missouri, demonstrated his method of suturing, on the board. He passes one suture through all the tissues, and maintains that it can be done so as to secure as nearly as it is possible to do it coaptation of peritoneum to peritoneum, fascia to fascia, etc. The skin is retracted, and the needle passed in sloping towards the median line.

VAGINAL LIGATION OF A PORTION IN THE BROAD LIGAMENT OF THE UTERUS FOR UTERINE TUMORS.

Read in the Section of Obstetrics and Diseases of Women, at the Forty fourth Annual Meeting of the American Medical Association.

BY FRANKLIN H. MARTIN, M.D.
CHICAGO.

The operation consists in the ligation from the vagina of more or less of the broad ligament with its vessels and nerves, the extent of the ligation depending upon the result sought, from a simple ligation of the base of the ligament, including the uterine artery and branches of both sides, without opening the peritoneum, to a complete ligation of the ligament of one side, including both uterine and ovarian arteries, with partial ligation of the opposite ligament, without opening the peritoneal cavity, if possible, but doing so if necessary.

The doctor reported five cases; two of these were reported in his first report of the operation. The result in the five operations were given up to date.

Case 1, in which the operation was incomplete on account of insufficient ligation of one ligament, has not resulted as

favorably as one could wish. Tumor not materially affected. Hemorrhages ceased temporarily. Subsequent reports show hemorrhage increasing again. The patient thinks that the tumor has increased somewhat. Dr. Martin has not had an opportunity to examine the patient in several months. On the whole the hemorrhage is less than formerly and the tumor not materially increased, although the operation cannot be said to be a success.

Case 2.—Patient had large tumor, eight by five inches in diameter and suffered severe pain and constant hemorrhage for several years. In a state of complete invalidism.

Patient left hospital on the eighth day. She was operated on the 3rd of December, 1892. I have seen this patient every month since the operation was performed. The hemorrhage has ceased completely. There has been very scanty flow at the menstrual period. All pain has ceased. The uterus had materially reduced in size at the end of one month. At the end of three months it was but little larger than a normal uterus. The patient's health has improved so that from a state of almost complete invalidism she was transformed into a comparatively strong and healthy woman. The improvement was progressive from the day of the operation.

Case 3.—Was sent to me by Dr. Stanley of Missouri. Patient married woman of about 30, no children, with a bleeding interstitial fibroid of the uterus enlarging that organ to diameter of four by three inches. The tumor was so comparatively small I decided to ligate but one side. The patient was out of bed in ten days. The results have not been ideal. The flow has been decreased in quantity. One month after the operation at the time I saw her last there has been no appreciable change in the uterus. She writes four months after the operation, the flow is about one-third the time in duration, and one-third the amount that it was formerly. Otherwise not improved.

Case 4.—Mrs. S., aged 36, menstruation has always been profuse and has been constantly increasing since the age of 20. Last five years till thirteen months ago has had profuse flowing, twenty-one days in each month, while the last thirteen months it has been constant and exhaustive. Patient confined to her bed. Suffers severe pain much of the time. December 19, in the presence of the post-graduate class I made an exploratory for the purpose of removing a uterine tumor if possible or of removing the appendages. I was unable to accomplish either operation on account of universal intestinal adhesions over surface of the growth. The abdomen was closed and when the patient was sufficiently recovered to stand another operation I performed my operation upon her. This was January 5, 1893. On account of the comparatively large sized tumor filling as it did the pelvis almost completely and extending to the umbilicus above, the operation was a difficult one. I succeeded, however, after considerable dissecting in including the entire base of each ligament with its principal blood channel and branches. The flowing ceased immediately and the patient was relieved of her drain for over two weeks.

She then had a few days flowing which resembled an ordinary menstruation. She has rapidly and steadily improved since that time. She has menstruated regularly but scantily and without pain. She can at this time, five months after the operation, attend to her duties as a housewife, and considers herself cured. The tumor has reduced in size until it is no longer noticeable as a deformity and so that the patient herself is no longer conscious of its presence.

Case 5.—German, married, age 30. When referred to me by Dr. Geer of Chicago, there had been constant hemorrhage for three months; diagnosis, fibroid tumor about size of four months pregnancy. Patient operated on January 5, 1893. Had a little subsequent temperature, and one month after ligation from left broad ligament came away from becoming infected from the vagina. Four months after operation the menstruation only lasted two days, very scanty, no pain. Fibroid diminished in size until uterus is about normal. Patient claims that she is cured.

NEW HOSPITAL FOR INSANE.—At the last session of the Michigan legislature there was appropriated \$75,000 for the establishment of a new hospital for the insane, the present accommodations being overcrowded. There are now confined in the Kalamazoo asylum 1,100 patients; Pontiac 900; Northern asylum at Traverse City, 600; criminal insane at Ionia, 250; Wayne county, 250; Dearborn, 100; scattered in jails and county houses, 2,000. The increase of insanity in the State is from 150 to 200 cases annually.

THE MANAGEMENT OF PATIENTS AFTER CELLIOTOMY.

Read at the Section on Gynecology and Obstetrics, at the Forty-fourth Annual Meeting of the American Medical Association.

BY CAREY KENNEDY FLEMING, M.D.

LECTURE ON CELLIOTOMY AND ASSOCIATED OPERATIONS, AS GIVEN AT DENVER, ARIZONA, ST. LOUIS, AND AT A HOSPITAL FOR GYNECOLOGY, IN DENVER, NOVEMBER, 1892.

In looking over the ground for a subject to present to the Section on Gynecology at this year's meeting of the American Medical Association, I have had two objects in view: first, that the subject should be one of common interest, and second, that it should be brief. For these reasons I have selected the above title for my paper.

The remarks to be made are based upon my own experience, and one hundred cases of celliotomy occurring in the practice of Dr. Thomas H. Hawkins of Denver; and I have been fortunate enough to have had the opportunity of studying the after treatment of each case. These cases have varied, covering the whole range or field of abdominal surgery. I cannot hope to offer anything original, but if I succeed in bringing out a discussion of the subject, possibly I will be pardoned for reading before you a paper so imperfectly prepared.

The first symptom requiring our attention after the patient has been placed in a warm bed, and recovered from the anæsthetic is nausea and vomiting. For this serious and sometimes alarming sequela we have been in the habit, as a preventive measure, of administering just before giving the anæsthetic, the following prescription:

R. Tinct. nucis vom. gtt. xv—xxv.
Spts. frumenti, 5 i.
Sig.: Before giving anæsthetic.

This, in some cases, acts beneficially in preventing the nausea and vomiting after the operation, and especially so when ether has been the anæsthetic. This vomiting is sometimes quite persistent, requiring the greatest ingenuity on the part of the surgeon to combat it, also harmful to the patient, both from its depressing and mechanical action. For this condition it has been our custom to administer hot water frequently in tea-spoonful doses, this in some cases acting quite nicely; carbonated mineral waters have also served a good purpose; champagne gives good results when there is or has been a tendency to collapse. Ice water or sucking ice I believe to be decidedly harmful. Morphine injections have been recommended by some writers, but according to our experience the secondary effects are most deleterious, always increasing the nausea.

Thirst. A condition which annoys the patient as much as nausea, is controlled somewhat by leaving the abdomen well filled with warm or hot sterilized water (if it has been necessary to flush out the abdominal or pelvic cavities); this fluid or water is rapidly absorbed by the peritoneum, quenching the thirst to a considerable degree; warm water per rectum acts often in the same way, while water administered by the mouth increases the nausea, making matters decidedly worse; the less we put into the stomach for forty-eight hours after the operation the better.

Pain.—Shall we give opiates to control the pain? I answer emphatically, no, excepting with those patients who have acquired the morphine habit, and of course in this class of cases it is necessary to give

morphine hypodermically in doses sufficient to control them. Morphine or opium, I believe, except in that class of cases previously mentioned, kills more patients than do celiotomies: it prevents secretion and elimination as well as stops peristalsis, causing increased thirst, nausea, tympanitis and increases the danger of sepsis and peritonitis. Restlessness is more urgent call for narcotics than is pain. In those cases where we are unable to control the patient otherwise, we are in the habit of giving fifteen to twenty drops of the deodorized tincture of opium per rectum, as often as is required.

Laxatives.—The use of laxatives may be commenced as early as the second day and certainly not later than the third day after the operation, and continued until peristalsis is re-established. For this purpose it has been our custom to give small doses of calomel in powders of one-tenth grain each every hour until we get the desired effect. Some patients are unable to take calomel without causing nausea: this being the case we rely upon salines and rectal enemas of warm water, sometimes containing glycerine and sulphate of magnesia. The bowels should be moved thereafter at least once in two days.

Drainage.—In regard to drainage in abdominal section we are accustomed to use either of two methods: first, the sterilized glass tube; second, sterilized iodoform gauze. The tube being used in those cases where pus has escaped into the peritoneal cavity, and the gauze in those cases in which we have had considerable hemorrhage, or where we fear or anticipate secondary hemorrhage, as in "bleeders," or to pack abscess cavities.

The glass tubes are usually removed in twelve hours unless otherwise indicated, and the abdomen closed by a suture which has been kept in situ for that purpose. In those cases in which the gauze has been used its removal is commenced on the second day and removed gradually, taking from twenty-four to forty-eight hours to remove the first packing. This, if necessary, is replaced by a smaller quantity and the track allowed to heal from the bottom by granulation.

Tympanitis.—A very important question is, how to prevent colic or abdominal distension after these operations? One important preventative is to refrain from the use of opiates for as I have already mentioned opiates paralyze the peristalsis, causing the accumulation and retention of gases in the intestines, giving rise per se to more or less abdominal uneasiness and pain and interfering with the peace and comfort of the patient. For this troublesome condition we have used quinine enemas or hot water injections, and the use of laxatives, as already mentioned, for as soon as peristalsis commences flatus is passed and the patient becomes quite comfortable. I will say in this connection, that the long rectal tube, as advised by some writers, has been but of little use in the majority of our cases. We have received more benefit from the rectal injections of a pint of warm water containing the sulphate of quinine in 10 grain doses, repeating the enemas of warm water in four hours if necessary, and the quinine twice in twenty-four hours.

Reopening.—The indications for reopening, I consider to be as follows, viz: hemorrhage, sepsis and peritonitis. When secondary hemorrhage occurs, the symptoms are the same as from hemorrhage of

any other wound; if the symptoms cannot be controlled it is our duty to reopen and flush the abdominal or pelvic cavities with hot sterilized water; this acts as an astringent and removes the clots. Afterwards pack thoroughly with iodoform gauze in the region where the greatest surface has been denuded by separation of adhesions. This has always controlled secondary hemorrhage for us. If the hemorrhage should be caused by the slipping of a ligature from the pedicle, the bleeding stump must be caught and a new ligature applied, afterwards removing all clots from the abdominal cavity by flushing with the sterilized water.

Not having had much experience with sepsis following celiotomy, my remarks will necessarily be limited. Still, I believe reopening and flushing out to be indicated as well as active purgation by the use of salines. In cases of general or local peritonitis the cause is undoubtedly sepsis, consequently the treatment is to reopen and flush out the abdominal or pelvic cavities and any pus pockets which may be found, also use salines to produce active purgation.

Diet.—In regard to the diet, as I have stated previously, the less we put into the stomach for the first forty-eight hours the better, either in the way of foods, drink or medicaments.

After the first two days if there is no nausea present any liquid food, such as milk diluted with lime water, kunyiss, broths and teas are very acceptable to the patient, but if nausea is present rectal feeding of predigested broths or milk is indicated.

If we are careful at the beginning in feeding our patients, it is only a question of a few days until they can have almost any easily digested foods they may desire.

SUSPENSIO UTERI.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY H. A. KELLY, M.D.

PROF. GYNECOLOGY AND OBSTETRICS, JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD.

Cases of retroflexion of the uterus which can not be relieved by palliative treatment, and in which there is good reason to believe that the position and posture of the uterus have a causative relationship to persisting aches and pains, are suitable cases for the operative treatment of the retroflexion.

It should be accepted as a cardinal fact that no retroflexion should be treated by a direct operation when associated with a relaxed vaginal outlet unless the latter be repaired at the same time or as soon after as possible. In some cases it will be proper to lift up the vaginal outlet, neglecting entirely the retroflexion. In other cases the retroflexion and the relaxed outlet will be treated at the same sitting.

The best operation for retroflexio uteri is the one which is applicable to the greatest number of cases, producing the largest percentage of recoveries, and the best permanent results with the least risk.

The operation which I shall describe answers these requirements more fully than any other. It is simple, not dangerous, and its results are uniformly good.

An incision two inches long is made in the median line of the abdomen nearer the symphysis than in an ordinary celiotomy.

After incising the peritoneum it is caught at the middle of the incision on either side with a pair of

artery forceps and pulled outside the wound, and the forceps dropped in the abdomen. This insures enough peritoneum remaining after the suspension of the uterus to allow the perfect closure of the abdominal wound, otherwise the sutures used to suspend the uterus tend to rob this part of the wall of its peritoneum.

The finger then glides down behind the symphysis over the top of the bladder on to the anterior face of the retroflexed uterus, which is hooked up and drawn forward into antelexion. Two sutures of medium sized silk are used for the suspension.

The abdominal wall on the left side of the incision is hooked up by two fingers until its peritoneal surface is exposed within for an inch. Then with a small, stout, curved needle the suture is passed so as to grasp about one-quarter of an inch of the peritoneum, and some of the fibers of the rectus muscle. The fundus uteri lying behind the symphysis is exposed by crowding the intestines back with fingers, retractors or sponges on stalks, the needle is then boldly passed through a portion of the posterior surface of the uterus below the fundus, about the same amount of uterus being included as that taken up on the abdominal wall; the suture is then drawn through, and finally the peritoneum and a part of the rectus are caught as on the opposite side of the incision. The suture is drawn taut and at once brings the uterus snugly up in slight antelexion to the abdominal wall and at the same time approximates the three peritoneal surfaces (uterus, and abdominal wall on both sides) transfixed by the suture; the suture is then tied and a second, which is introduced with greater facility than the first, transfixes the uterine tissue a little below the first, and thus when it is drawn up to be tied, lifts the uterus a little farther into antelexion. When the sutures are both tied, the finger is introduced into the abdominal cavity and a careful examination is made to see that the intestines and omentum have not been caught at any point above or in front of the uterus. The peritoneum and the abdominal wound are closed in the same manner as after an ordinary celiotomy. The uterus is thus suspended in antelexion to the anterior abdominal wall by two buried silk sutures. A few weeks later the uterus is found upon vaginal examination to be in a position of easy mobile antelexion, without any apparent connection with the anterior abdominal wall.

I have taken for criticism in this connection all my cases operated upon by any abdominal operation in the Johns Hopkins hospital, not including those performed since the first of the year. Out of eighty cases referred from the dispensary by my assistants and from private practice by myself, forty-four were found suitable for operative treatment.

Forty-seven operations were performed; three cases requiring a second operation. Twenty-eight were married women; sixteen were single; twenty-eight had borne children and averaged about three each.

There were no deaths, and as far as I have been able to learn, no discomforts arising from the operation.

A simple suspensory operation was performed in twenty-three cases. Other operations were performed at the same sitting in twenty-one cases.

SURGICAL TREATMENT OF UTERINE FLEXIONS.

Read in the Section of Obstetrics and Diseases of Women at the Forty-fourth Annual Meeting of the American Medical Association.

BY M. B. WARD, M.D.

PROFESSOR OF GYNECOLOGY IN THE KANSAS MEDICAL COLLEGE, TOPEKA, KANSAS.

It is my desire to briefly consider the propriety of doing an abdominal section, in suitable cases, for retro-displacements of the uterus.

It is, perhaps, unnecessary that I should preface my remarks with the statement that he who dares to recommend such radical measures for an ailment so insignificant in character, is certain to be severely criticized, and perhaps charged as having an unnatural desire to use the knife when milder measures meet all the indications. It is better, however, to give our views in our own way, from our own standpoint, and cultivate that generous spirit which allows others to do the same.

In my experience, it has been extremely difficult and very often impossible to afford permanent relief in a large majority of cases of chronic retroflexion, by methods usually recommended. It is comparatively easy to give temporary relief in many cases, if we will persistently treat the patient by placing her in the knee-chest position, and gently raise the fundus and tampon the posterior vault with cotton wool, saturated with boroglycerine. I refer to this method because I consider it a good, if not the best plan of treatment. When it is impossible to replace the uterus in the normal position on account of adhesions, this treatment softens the adhesions, relieves engorgement and gives comfort. But the larger number of our patrons will give histories of long suffering, many attacks of pelvic peritonitis—some mild, and some severe—which will readily indicate that serious complications must be overcome before the uterus can be brought forward to the normal position. It is this class of cases that I am considering in this essay.

What shall we recommend as the best plan of treatment? My custom is to say to the patient that the local treatment will give comfort and, if she can exercise due patience, she *may* be permanently relieved. I always inform them of the possibility of failure. The next plan recommended is to do an abdominal section, break up the adhesions, remove the appendages—if they are diseased, bring the uterus forward and close the abdomen, all of which may be done in a few minutes safely—and your patient will speedily and permanently recover. I am again anticipating unfavorable criticism on account of the apparent unconcern which I manifest toward those much talked about little organs—the ovaries. I do not wish to be understood as one who ignores the right inherent in every woman to possess these, as well as all other organs which of right belong to her; but I do wish to be placed in that class who throw aside sentimentality and treat conditions in a common sense and scientific manner. When surgical measures are indicated as the only source of relief, we should not refuse to employ them, even though it may be found necessary to remove organs adjacent to the uterus. Let me explain still more fully my views on this subject. Many times an operation by section for retroflexion may be successfully performed without the necessity of removing the appendages, but it will be necessary in these

cases to take extra precaution against a recurrence by fixing the uterus in its normal position, by shortening the round ligaments, or by ventral fixation. I should not by any means remove healthy ovaries when operating for retroflexion by the section method. Should I find the ovaries diseased, then I would not hesitate to remove them. There is a proviso, however, that I wish to insert in this connection, namely: when the patient is young and would naturally wish to bear children, I should not then remove the ovaries, unless they were so altered by disease as to make fecundation impossible. In view of the fact that it is not always easy to define the extent of the destruction of normal ovarian stroma, we should give the would-be mother the benefit of all doubt and leave undisturbed the suspicious ovary. On the other hand, should the patient be the mother of several children—and there is no reason why she should have more children, unless she herself desires them, I should not be so particular to give the suspicious ovary a chance to assert its normal function, if to remove it would promise great relief to the sufferer.

From my no inconsiderable experience, I am prepared to make the statement, that it is only occasionally necessary to make the fine distinction before mentioned, for in nearly all cases of chronic retro-displacements, the appendages are seriously involved and therefore diseased beyond any question.

The most satisfactory feature of the operation now under consideration, is the fact, almost universal, that the uterus will remain permanently in the anterior position without support, if the appendages are removed. It is surprising how emphatically nature asserts herself when the *guy ropes* are cut which hold the uterus in abnormal position. Immediately the uterus will go forward—almost with a bound—and reminds one of a sapling that has been bent to the ground and held, but which quickly returns to the upright position as soon as the force which binds it down is removed. So charming are the results of this operation in cases where the patient has suffered greatly for years, and has been subjected to all sorts of methods of treatment, and without permanent relief, until she has formed unfavorable opinions of the profession, that he who relieves her by this method is classed, and justly too, with the greatest of benefactors.

The next objection to this method, which I anticipate will be advanced is, that the danger to life is too great to operate in the abdomen for a condition which does not, of itself, destroy life, but only causes suffering and perhaps may do permanent harm only by establishing nervous sequelæ; this is the most important question to be considered in this connection. If it is a fact that the operation recommended is to result fatally, then of necessity we should only perform it as a dernier resort. But I contend that this operation should not give any greater mortality rate in properly selected cases than would amputation of a finger in properly selected cases. What I call properly selected cases, are those who have the endurance which will justify us in doing any kind of surgical operation of sufficient magnitude that complete anaesthesia and confinement in bed for two or three weeks would necessitate. That there is a degree of danger in any operation goes without saying and, therefore, it would be a mistake to assure the patient and friends that there

is not some danger in this method; but it could be said with propriety that in the uncomplicated cases the mortality is about nil. Not more than 2 per cent. should perish. It is customary to fortify one's statements, when treating of a subject of this character by reporting cases, and I should gladly do so on this occasion, except for the reason that it is entirely unnecessary in view of the extensive experience of all present. Suffice it to say that there are a goodly number of ladies in my State who would gladly make testimony touching the renewed health—almost renewed life—they are enjoying; the result of this operation. No death has occurred to dampen my ardor, but I am always and at all times looking out for possible complications, by stating to the patient and friends that something may occur, and am on my guard, expecting something to occur that would cause all to grieve.

It is possible that I should have occupied more of the valuable time of this Section by a more detailed and elaborate classification of cases that should be subjected to abdominal section for the cure of displacements of the uterus; but I am obliged to leave to the generosity of my confrères to give the essayist the benefit of the doubt—as we would say in law—and convict him by trial before pronouncing judgment. In other words, I am not anxious to operate in the abdomen, if other methods less dangerous can be employed with good results.

PROLAPSE OF THE FEMALE PELVIC ORGANS.

Read in the Section of Obstetrics and Diseases of Women at the Forty-fourth Annual Meeting of the American Medical Association.

BY HENRY PARKER NEWMAN, M.D.

Prof. of Gynecology, Chicago Post-Graduate Medical School; Prof. Clinical gynecology and Obstetrics, College of Physicians and Surgeons; Gynecologist to Chicago Public and West Side Free Dispensaries; Physician and Surgeon to St. Elizabeth Hospital; Surgeon, (department diseases of women) Chicago Post-Graduate Hospital; Secretary of the Chicago Gynecological Society; etc., etc.

It is my desire to call attention, briefly, to prolapse of the female genital organs, with particular reference to their hernial nature; regarding them as having a similar etiology, and the same pathological significance as hernia in other situations, and amenable to analogous lines of treatment.

The classic division of hernia into cephalic, thoracic and abdominal is incomplete without the important group comprised in the title of this paper; and, in view of their frequency and importance, they should enjoy an individual classification in herniology.

For accuracy and convenience, we would designate four major classes: cephalic, thoracic, abdominal and pelvic hernia.

The etiology of these affections, in general, comprises such predisposing and exciting causes as defective development, including congenital malformations and inherited tendencies; depraved muscular tone through debilitating disease, and trauma.

While the majority of cases are generally attributed to traumatism, this may often in itself be the result of defective development, and inherited or acquired weaknesses or malformations.

Again, defective development represents not only the malformations of foetal life, but the results of arrested growth at the period of ripening or puberty.

Nature aims to furnish at birth suitable rudimentary pelvic organs, and it is exceedingly seldom that she fails to do so.

In the interference of artificial influences with the natural formative conditions of puberal activity, it is to be found the proper explanation of many abnormalities of development.

It is an error to designate them as fetal malformations. Under existing conditions of custom and education the female pelvis, with its complex mechanism and its importance to the race, receives altogether insufficient recognition and conservation during puberty and adolescence.

Consequently, it is too poorly fortified against the demands made upon it during menstrual and child-bearing epochs.

In the face of our boasted civilization and enlightenment, we must admit that the representative of budding womanhood who is addicted to corsets, heavy skirts and high-heeled shoes; lives on hot bread, pastry, pickles and sweetmeats; and, in our cities, is in the highest grade at school, up six flights of stairs; and burns the midnight oil in the pursuit of knowledge or pleasure, is not the exception but the rule.

She is either ignorant of, or oblivious to the fact that she has an important set of generative organs which will probably be called upon one day to fulfill the purposes of their being, and that the proper performance of their future functions depend largely upon the judicious care bestowed upon the general health during the crises of development.

Rational treatment, therefore, of most gynecological diseases may begin before the affection has reached the surgical stage. This is particularly true of pelvic hernia. An ounce of prophylaxis is worth a pound of pessaries.

The general practitioner, the family physician, has his opportunity before the specialist, and it is for him, when occasion offers, to urge upon the parents and guardians of young girls the necessity of attention to the regimen of the actively formative period of puberty.

Good food, sensible dress, a proper interchange of exercise and rest,—insist upon these things, general practitioners, for the sake of humanity's ultimate good, even if you take some bread out of the mouths of the specialists, into whose hands most neglected cases drift. The humanitarian gynecologist can well spare it. But it is not probable that his entire revenue from this source will be summarily cut off.

There is another factor in the production of pelvic disease which will furnish enough of its own victims to "keep hot the pathway to the office of the gynecologist," to quote an apt expression from a recent writer in a western journal.

I refer to trauma in childbirth, and some of the prevalent evils of puerperal management, which render the normal process of reproduction a formidable menace to the after-health of the parous woman.

Many women whose puerperal histories go to make up some obstetrician's brilliant percentage of recoveries, have escaped (by the grace of God, and through no fault of the accoucheur,) with their lives, but with wrecked constitutions and dismantled pelvises.

These cases, with subinvolution and torn pelvic floor, loss of tonicity of uterine and vaginal supports,

furnish frequent examples of all degrees of pelvic hernia, and a strong argument in favor of preventive therapeutics.

In a former monograph I have referred to the excellent results to be expected from direct professional supervision over the entire period of gestation from the earliest months to the completion of labor.

But the consideration of prophylaxis in pregnancy, childbirth and the puerperal state is not the object of this paper.

I have wished simply to indicate its relation to downward displacements of the pelvic contents, and would emphasize the fact, once more, that it is easier to prevent such conditions than to remedy them.

Guard against the possibility of ruptures and lacerations during labor; repair at once such as are unavoidable; and use every effort to secure proper involution and a return of constitutional tone and muscular vigor, as far as is consistent with a normal puerperal state.

For the actual existence of pelvic hernia,—cystocele, rectocele, prolapse of uterus and vaginal walls,—prognosis and treatment depend upon the nature, degree and duration of the condition.

Much may be done in all cases, (minor cases of recent origin may sometimes be cured,) by systemic treatment, attention to regimen, tonics, massage, faradism, local astringents, and removal of weight and constriction from the abdomen, with the view in all cases of encouraging the retentive power of its walls.

Proper action of the pelvic diaphragm is essential to the healthful condition of the pelvic viscera.

This cannot be accomplished with constriction at the waist, or any impediment to free abdominal respiration.

All local treatment has for its aim the restoration of the prolapsed organ, and its retention in the normal position.

A hernia is a surgical disease and calls for surgical treatment, which admits of wide interpretation and includes all mechanical means from simple air-pressure and gravitation in postural treatment to the radical operation of removal of the offending organ.

Simple restoration can usually be accomplished by taxis, preferable in the genupectoral position.

Exceptional cases, such as uterine prolapse with inversion, hernia with adhesions or incarceration, may prove irremediable, and require special treatment, palliative or radical, as best suited to individual indications.

The retention of the replaced organ is not always an easy matter, and calls for great judgment in the selection of appropriate methods.

The simple tamponade, combined with astringents and medicinal agents is extremely useful as a palliative measure, and in the treatment of complicating disorders, as chronic congestions, hyperplasias and inflammatory exudates.

But we can hardly expect permanently gratifying results from their use, except in recent and minor cases.

The same may be said of most other therapeutic agents and mechanical appliances, including the much-abused pessary.

The idea of both pessary and tampon is based upon the supposition of auxiliary pelvic support for its retention.

This is, unfortunately, just what is lacking in most cases, and steps must be taken for its restoration before either can be satisfactorily used.

The operation of perineorrhaphy, as done to-day is simple in technique, quickly performed, and efficacious in restoring the perineal body, and even where the laceration is complete is rarely followed by any but good results, if done for rectocele, or prolapse of the posterior vaginal wall.

In the same way the various colporrhaphies are most excellent in their sphere, that of reducing the volume of relaxed and prolapsed vaginal walls, but we mistake the pathology when we regard colporrhaphy as quite analogous to perineorrhaphy.

The latter removes the cause of the affection for which it is done, while the former may or may not do so.

In one instance we operate upon a substantial body, capable of sustaining the prolapsed viscus which had escaped by reason of the laxity or laceration of that body; while in the other, we have to deal with simple mucous membrane which, sooner or later, must again yield to the same opposing forces, unless the cause be removed.

It is even more fallacious to expect simple constricting of the vagina to remedy a hernia of the uterus, without any attempt to restore the anatomical relations of the parts, particularly the correct angle of uterine and vaginal axes.

A large and heavy uterus, with its abdominal supports weakened and stretched, and fundus and cervix perpendicular to the pelvic canal, will soon burrow its way through the cicatricial vaginal tissue by its own weight, supplemented by the vis-a-tergo of intra-abdominal pressure.

This tendency can be happily overcome by bringing the fundus forward into its normally anteverted position.

The three most serviceable operations to secure this result are, shortening of the utero-sacral ligaments; abdominal fixation of the fundus, or ventrofixation; and shortening of the round ligaments.

The latter, which is known as the Alexander-Adams operation has more to recommend it, in my judgment, than any other procedure.

It is founded upon the principle not of suspending the uterus, but of using the round ligaments as guy ropes to steady the organ in its normal anteverted direction, and bring it into auxiliary relation with the natural retentive forces of the abdomen.

The operation is simple of accomplishment, may often be done without general anaesthesia, and has given me such uniformly satisfactory results that I heartily recommend it to those who desire to master its improved technique, which I have already detailed in former publications.

In conclusion, I would re-emphasize these points:

1. Pelvic hernias should be recognized and classified as such, and not as diseases of the uterus and adnexa; and their treatment should be based upon hernial pathology.

2. Prophylaxis, in the formative stage of puberty, as well as in pregnancy and labor, is of the utmost moment in this class of cases.

3. Operations upon the pelvic floor or vaginal walls, while indispensable in their place cannot be relied upon alone to cure all hernia of the pelvic viscera.

4. The ideal treatment is to be found in the com-

bination of operations for repair, and those for accessory support from above, and these may all be accomplished at the same sitting, saving the delay and annoyance of repeated operations.

Venetian Building, Chicago.

VESICO-VAGINAL FISTULA: ITS ETIOLOGY AND TREATMENT.

Read before the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY AUGUSTUS P. CLARKE, A.M., M.D.

CAMBRIDGE, MASS.

Vesico-vaginal fistula may be described as a pre-natural opening between the bladder and the vagina. The communication may be located at the cervix or at the fundus of the bladder. Sometimes an opening from the urethra into the vagina takes place; an opening thus established is usually smaller and less jagged than is one situated in the neck or in the fundus of that viscus. Urethro-vaginal fistula may result from the compression to which the parts are exposed during parturition. It will be observed that the urethra in its oblique descent under the arch of the pubes toward the meatus urinarius occupies for some distance the anterior portion of the vaginal wall; this position exposes the urethro-vaginal tissue to many accidents during a difficult or tedious parturient process.

In those cases in which the fistula is situated in a higher segment of the bladder, sloughing that has often caused an opening may have been superinduced or hastened by labor. Many conditions which are dependent on pregnancy favor the development of fistula; such conditions predispose to disease the vesical tissues which finally require only the super-vention of parturition for an actual occurrence of the morbid process.

An acute cystitis may come on during the course of pregnancy; in such cases there may be an extended vascular injection of the mucous tissue. Brownish or discolored patches may occur in the vicinity of the neck and fundus of the bladder; there will occur at first more or less induration or alteration of the vesical walls, and later there will be present a fibrinous and purulent exudation at different foci or in areas in which serious and degenerative changes have taken place. The disease may be limited to the mucous lining of the bladder; in cases in which there may be some renal complication the morbid process may penetrate the layers of the muscular coat and involve the peritoneum posteriorly in its upper zone or may implicate the vaginal wall anteriorly in its lower section. Suppuration may be dependent on the presence of minute abscesses occurring in the parietes of the bladder; ulcerative processes may also have so continued as to have led to softening, maceration, commencing gangrene or destruction of portions of the mucous and subjacent muscular structures.

Not long since I was called to an autopsy of a woman aged 37 years; she had died of acute pneumonia complicated with other serious troubles. There was found a degenerative change which had taken place midway between the fundus and the neck of the bladder. The mucous, the connective and the muscular plains in limited areas were observed almost entirely destroyed; the integrity of

the organ was only kept intact by the vaginal tissues which also had become exceedingly attenuated. The patient had suffered from two miscarriages; there was also a recent corpus luteum. There was no history of unusual suffering from vesical disturbances. It is, therefore, fair to presume that had the last pregnancy continued until the end of the full term, the strain upon the tissues incident to parturition, however carefully managed, would have been followed by the appearance of a vesical opening through the vaginal wall. Chronic cystitis may result in vesical fistula. The irritation excited in the mucous coat effects an alteration of the membrane; the parietes become thickened, indurated and from the exudation of matter the parts assume a fatty or homogeneous appearance. Ulcerative and suppurative processes are liable to supervene and finally lead at some point to the presence of complete fistula.

I have notes of an autopsy on the body of a lady aged 36 years, who having suffered from the effects of chronic cystitis died of cardiac disease. The kidneys were found to be congested and to be in the initial stage of granular degeneration. The bladder was somewhat contracted; the mucous tissue between the neck and fundus had undergone degenerative changes. The epithelium or basement membrane in patches was destroyed; the muscular tissue beneath was implicated. Narrow bands of the muscular coat which had been deprived of its interstitial and connective tissue could easily be caught up on a small probe. The vaginal wall in places was much thickened, while in other places it was well nigh perforated; the bladder contained a considerable quantity of urine, though the vaginal wall opposite the ulcerated points was exceedingly attenuated. The autopsy was made twelve hours after death. The patient had suffered from an accidental abortion and had also borne one living child since she first began to suffer from the cystitis. Her entire escape from an actual occurrence of complete fistula through the vaginal wall considering the pathological condition of the cystic tissues was indeed remarkable.

Emmet¹ formerly attributed in large measure the occurrence of vesico-vaginal fistula to childbirth. Out of 202 cases which came under his care at the Woman's hospital in New York, 171 were ascribed to this cause. He considered the condition of the bladder often affected the progress of labor. When the bladder was distended the labor would be retarded and would consequently prove an indirect cause of fistula. Marriage, late in life, he also considered may have some relation to the accident. The progress of labor occurring after such late marriage, may be retarded through want of elasticity in the soft parts. Instruments employed to terminate labor have been regarded as another cause. According to my own experience, however, it is difficult to see how the proper employment of instruments can enter into the factorage of causes when it is considered that such agencies brought into activity do materially abridge the hours of labor. It is an undoubted fact that the duration of the parturient process exercises an important part in the causation of vesico-vaginal fistula for the reason that the injury is often incurred in the first or in the second labor.

In cases in which the labor is unduly prolonged,

neglect to empty the bladder at proper intervals may be laid down as an exciting cause of the accident. This should be regarded as especially so in those cases in which there has been cystitis. Some nurses who have been regarded as well trained, and even physicians of extended practice, occasionally fail in preventing in labor the bladder from becoming unduly distended. The reason given for such course in attendance is the fear that when the use of the catheter has once been resorted to it will have to be continued. This practice with such has been followed not only during the hours of labor but after its termination also, provided the patient has not demanded immediate help on account of severe suffering, or has not given indication of some passage of urine. Though in my own practice I endeavor to abstain from becoming too officious and from interfering with nature's normal processes yet I cannot but entertain much solicitude respecting the condition of the bladder especially in those cases in which there has been a history of recent cystitis. By following this method of procedure in a series of 2,500 consecutive obstetric cases coming under my care during many years of my private practice I have succeeded in preventing in every instance the occurrence of a vesico-vaginal fistula. In two cases which have come into my practice for treatment the fistula was caused by the removal of calculi through an excision above the neck of the bladder. In one instance a fistula was produced by an abscess occurring in the vaginal fornix. The opening, however, finally closed spontaneously. In one case to which I was called the injury was the result of an accident to the patient; she fell on a sharp instrument which piercing the right labium majus penetrated the vaginal wall just over the neck of the bladder. The length of the wound was nearly two centimeters. The application of sutures of annealed iron wire gave partial cure, which was subsequently completed by the employment of aseptic sutures of kangaroo tendon.

For severe cases of chronic cystitis Emmet's operation for artificial vesico-vaginal fistula is a valuable expedient. The chief objection to this method of treatment according to the records of my own cases is the difficulty in effecting a speedy closure of the incision, for when the opening has been allowed to remain for several months, without closing, the bladder becomes pre-naturally contracted; the tissues also become thickened and indurated. Sometimes this condition of the structure of the bladder has supervened before the artificial opening has been made. With such factors to be dealt with the ordinary methods employed for closing the incision are often found in great measure ineffectual. A. F. McGill,² F. R. C. S., surgeon to the Leeds Infirmary, has given a description of an operation for vesico-vaginal fistula through a supra-pubic opening in the bladder; the operation is conducted somewhat after Professor Trendelenburg's method for supra-pubic cystotomy. Two cases are mentioned; the first operation was necessitated for the closing of a fistulous opening through the vaginal wall, accidentally made while attempting to remove an epithelioma involving the floor of the urethra for its whole length as well as part of the anterior vaginal wall, and base of the bladder. The edges of the fistula were brought into apposition by means of supra-pubic drainage

¹ Principles and Practice of Gynecology, 1870.

² Lancet, 1884, 10, 100. See Retrospect, part xxiii.

a complete and spontaneous cure resulted. The other case was an ordinary one; the injury followed labor. In this the operation through a supra-public incision into the bladder effected a cure. In cases in which a repeated operation fails to give relief the author advises that this method should be tried.

William Duncan 'M.D., M.R.C.P., assistant obstetric physician at the Middlesex hospital, London, reports a case of extensive vesico-vaginal and recto-fistula cured by means of flaps dissected up as thickly as possible from the left side of the vagina with its lower end on the inner surface of the left labium majus. The flap measured one inch and three-quarters in length, and one inch in breadth. Carbolic lint was placed under the flap; eighteen days after the formation of the flap the operation was completed by freshening the edges of the opening into the bladder and fitting the flap to the fistulous track with the vaginal mucous membrane toward the bladder. Wire sutures were employed; a self-retaining rubber catheter was introduced into the bladder. The parts united and the fistulous opening was much diminished. Repeated attempts at operative interference finally effected entire closure of the bladder. The retro-vaginal rent was closed by taking a flap from the right wall of the vagina in a manner similar to the one taken from the left side. After the edges of the fistula had been pared the flap was fixed to the margin of the opening by means of silk and catgut sutures. This led to a perfect union and a final cure. The same author reports a case of vesico-vaginal fistula caused by extensive sloughing of the anterior vaginal wall. Closure of the vaginal wall after the method of Simon was resorted to for relief.

Hertel (*Francoeur*, 1888) after splitting the vesico-vaginal septum around the opening turned in the edges of the vesical and vaginal mucous tissues respectively. Each is united by deep and superficial sutures. Several advantages are gained by this method. Aside from splitting the septum around the fistula no further denudation is required. This method precludes the necessity of removing to any great extent the cicatricial tissue; by reason of this an important advantage is gained, for when there is much cicatricial tissue in the vaginal wall it is often quite impossible to effect its entire removal. The mucous membrane at its edges after the division of the fistulous septum can easily be brought together; the abraded surfaces after being placed in such apposition readily unite. By the adoption of this method there is no loss of tissue. The operation can if necessary be repeated; if unsuccessful the tissues will be found to have escaped from serious injury from the operative interference.

In an elaborate paper read at the Ninth International Medical Congress at Washington, 1887, by Dr. Nathan Boseman³ of New York, emphasis is laid on the importance of dividing the cicatricial bands which often interfere with an operation for the closure of the perforated tissues. Such cicatricial bands were regarded as productive of undue strain on the coapted parts; this would occur before the tissues had united sufficiently to insure success to the operative measure. Cases have been reported in which adhesions of the anterior or of the posterior

lip to some portion of the vaginal wall or fornix have prevented the uterus from being brought down to the lower segment of the vagina when an operative measure was undertaken for the closure of the fistulous tract. Inflammation from laceration or from other injury to the cervix may set up in the vaginal tissue the formation of constricting bands that will have to be overcome before an operation for the closure of the fistulous opening should be undertaken.

J. Marion Sims in his effort to bring prominently before the profession the advantages an operation affords for the relief of vesico-vaginal fistula, maintained that sutures of silver wire were the ones best adapted to secure favorable results. His operation was originally undertaken without the employment of antiseptic precautions. The unique results which he obtained were undoubtedly due in part to the use of metallic sutures; such sutures to a great extent are aseptic. The rapidity of his work and the exercise of rare skill with which it was often accomplished, compensated in large measure for deficiency in other measures of his procedure. Sims was by no means the originator of the operation for vesico-vaginal fistula. M. Jobert de Lamballe, the eminent French surgeon to the emperor, has described in his *Traité de Chirurgie Plastique* the operation which, as early as 1837, he performed for vesico-vaginal fistula. Mr. Gasset in 1834, gave in the *London Lancet* a good account of the operation. Sir James Y. Simpson also seems to have anticipated Sims in this line of work.

Since the employment of antiseptic precautions has been generally adopted silk sutures aseptically prepared have by many operators been largely used. Silk sutures however carefully prepared, are not altogether free from danger. The properties of silk are not easily overcome by the action of the living tissues. The interstices of the structure of silk are liable to be invaded by microorganisms before the margin of the wound has united sufficiently to allow the sutures to be removed. Aseptic animal sutures are much to be preferred. No suture in my own practice has given so great a satisfaction; the employment of aseptic catgut sutures in vesico-vaginal fistula often yields excellent results.

Kangaroo tendon prepared according to Lister's formula are for this kind of work incomparably the best. After splitting up the septum round the margin of the fistula the deeper or vesical portion of the tissue should be brought together by means of a medium sized tendon suture. The suture should be applied after the manner of the cordwainer's stitch. After the layer of sutures has been taken through the vaginal or external tissue of the bladder the first line of sutures will be entirely concealed.

The sutures employed for the vaginal wall should be somewhat smaller than those for the vesical layer, and should be applied by introducing the needle first into one lip of the wound some distance from within by passing outward close to the edges of the coapted parts. After the sutures have been introduced the tissues through which they have been taken should be in such close apposition as to conceal all traces of their appearance. The sutures will thus be protected from the action of the fluids from the vaginal wall. By the insertion of tampons of cotton or of iodoform gauze or wool the vulvo-vaginal introitus will to a great extent be rendered aseptic. Repeated

catheterization of the bladder at regular intervals will prevent undue strain upon the vesical and vaginal tissues; these measures of proceeding if properly carried out will materially help to establish a speedy and permanent cure.

RECENT PROGRESS IN ELECTRO-GYNECOLOGY.

Read in the Section of Obstetrics and Diseases of Women at the Forty-fourth Annual Meeting of the American Medical Association.

BY G. BETTOS MASSEY, M.D.

PHILADELPHIA.

The year's progress in the art of applying electricity as a remedy in the diseases of women has been of twofold character, embracing increased exactness in an art requiring technical knowledge of a high order on the one hand, and on the other an increased use of the remedy by conservative gynecologists. The allurements of a surgical ambition continue to operate as a bar to the higher electrical skill of some operators it is true, but a still greater number are becoming convinced that the diseases of women have a deeper significance than mere cosmetic accuracy of outline in pelvic organs; and that an agent capable of doing much in the cure of diseased processes, the relief of suffering and restoration of function deserves a more careful study than has been given to it by those who regard gynecology and surgery as synonymous terms.

RESTORATION OF FUNCTION.

It is too often forgotten that the highest art of the physician is shown in the restoration of normal functionation in an organ or set of organs. In the case of the pelvic organs of women, the disparity between the current literature devoted to the removal of more or less diseased members and their cure is very great and indicates, it is to be feared, that the lesser work replaces the greater in actual practice. The prevention of diseased action in organs is of course a still higher work, but while the busy physician may be pardoned for relegating preventive medicine in some measure to the hygienist, he should not be pardoned for neglecting possible cures of diseased organs and turning his attention exclusively to their ablation and amputation. One of the benefits conferred upon gynecology by the introduction of electro-therapeutics into its remedial armament, is the recalling of professional attention to healthier channels of therapeutic endeavor by the infusion of new hope in the efficacy of conservative methods.

In this agency we have a valuable remedy for the congestions and relaxations that interfere with pelvic functions, and lead consequently to more pronounced disease. Its control over abnormal menstruation is often successful where drugs have been found to be ineffective, and it may thus be of service in the removal of those conditions so frequently leading to positive disease of the ovaries or of the nervous system in early maidenhood. A mere external application of the galvanic current of large dose between periods, through scientifically adapted cutaneous electrodes, may be amply sufficient as a curative remedy in both amenorrhea and menorrh-spasm; but when this has been insufficient to cure in a given case, we must use the same method during the actual attack of menstrual pain. This almost invariably ends the immediate attack, though a per-

manently curative effect will require at times that an intra-uterine negative application be made, and my quickest successes have been attained when the application was made during the flow itself.

On the electrical treatment of menorrhagia and uterine hemorrhage I will not dwell, as its efficiency is generally conceded, though too often not used by those who continue to employ harmful drugs or curet-tage.

It is not a little strange that the classical treatises on gynecology, with the exception of that of Barnes, are practically silent on the disturbances of that function which, certainly next to menstruation and conception, is most closely associated with our practical work as gynecologists. In coming and defining the term *dyspareunia*, this writer, too, but touched on a considerable field of maternal impotencies, the bearing of which upon conditions and sufferings daily encountered is far more important than generally conceded. A little research in many cases of ovarian and lumbar pain in married women will point to this as a cause, even though periuterine tenderness or displacements may be present, and particularly if catarrhal conditions of the uterus and tubes are absent. A merely physical and passive performance of a function normally requiring a most delicate co-ordination of nerves, muscles and glands cannot be other than prolific of local congestions and more general nerve aches, and this result is often found in both participants, for a law of nature has been broken which even dogs obey. The causal conditions underlying dyspareunia are not merely hyperæsthetic conditions of the vulva, on which stress was made by Barnes, but also muscular relaxations of the vagina which make it impossible for the act to be reciprocal, leading to bruising and disturbance of the internal parts, and more or less pronounced nerve strain. The connection of electro-therapeutics with this subject is obvious. In the vaginal applications of both currents we have a direct exciter of the flagging energies of the constructor cummi and levator muscles and the circular fibers of the vagina, though care should be exercised that an over-long stimulation does not lead to fatigue. The swelling method of turning the current on and off is best, and the faradic current may be applied, either bipolar or monopolar, the coarse secondary or primary coils being selected in preference. Probably the most effective exciter is the combined primary faradic and galvanic, negative monopolar electrode, the indifferent pole being on the back. This method also relieves the congestion and tenderness in the uterus and ovaries while adding tone to the muscles.

In the treatment of maternal sterility due to catarrhal disease of the uterus the galvanic current may also be relied on as of direct service, in addition to the possible results that may be derived from electricity in the associated condition just described. The method is that employed in the treatment of endometritis, with or without accompanying menorrh-spasm, and its use will be found to be far more effective than the commonly practiced operations of dilatation, and less likely to be followed by diseased tubes and ectopic pregnancies.

THE RELIEF OF OBSCURE PELVIC PAIN.

Excluding the functional disorders that have been mentioned, acute inflammations and neoplasms, it will be found that most women apply for treatment

for chronic pains and distresses of a more or less indefinable character. It becomes the duty of the physician to ascertain the cause of course, but even in case the probable cause can be located by exclusion in the pelvis, he has no more right to inflict injury in ascertaining its exact nature or providing theoretical relief than when other parts of the body are affected. An increased employment of vaginal applications of electricity is advocated in these obscure cases, in preference to so-called exploratory abdominal sections, which so frequently result in the removal of ovaries that are but slightly or not at all diseased. The electrical application may cure the case by stimulating the activity of the absorbents, and thus removing remnants of unsuspected inflammatory processes that had given rise to the distress, or by a direct action on the pelvic nerves, and if it does not thus clear up the obscurity the patient is yet in good shape for other remedies. Non-suppurative inflammations of the appendages, even prolapse of the ovaries, indicate this method, and it is often curative. To the interpolary action of the current itself we may add the action of iodine, driven into the tissues from the positive vaginal electrode by the recently revived method of cataphoresis.

CHRONIC METRITIS.

The researches of electro-gynecology are, however, contributing towards a revival of the older views, which attributed to the uterus the chief place as the seat of chronic inflammatory trouble, as well as an avenue of infection for parts higher up. The light recently reflected on the diseases of the appendages by operative surgeons has rendered incalculable aid in diagnosis, but should not blind us to the possibilities of a continuance of the chief trouble within the uterus, demanding local treatment for its alleviation. The possibility of employing strong galvanic currents of more than fifty milliamperes for this purpose without creating unpleasant irritation, has been enhanced by the use of cotton covered elastic electrodes of platinum within the uterine cavity, the cotton having been saturated with a solution of cocaine if the endometrium is sensitive, or with a watery solution of an antiseptic agent. This simple expedient will permit of the addition of cataphoretic medication of the uterus to the galvanic application with results, so far as the addition is concerned, that are yet under judgment. The value of the current itself in combating endometritis and hyperplastic metritis is well established, and its more general employment will not only remedy a numerous class of cases of recognized uterine inflammations, but also render the operations of curettage and trachelorrhaphy and the wearing of pessaries of rare and infrequent utility.

FIBROID TUMORS.

With their accustomed alertness, American physicians have not only absorbed the French experiences as to the value of electricity in fibroid growths of the uterus, but have pushed the investigation farther, as evidenced by well-attested instances of actual disappearance of the tumors, several of which were reported during the year. The field of this remedy in fibroids is being more accurately delineated, as added experience teaches that it is most useful in the interstitial and intramural varieties, or when the subperitoneal buds are still sessile. But little effect can be expected in the subperitoneal variety, unless

the tumor is particularly well situated for either pelvic or abdominal puncture. Oedematous myomas, or tumors that have undergone cystic degeneration, are distinctly unsuited to electric treatment, and the same may be said of all such growths accompanied by purulent degeneration of the appendages; though simple non-purulent inflammations of the appendages do not constitute a contra-indication. The interstitial tumors, both hemorrhagic and non-hemorrhagic, in which electricity is curative form a large group, and the testimony of many recent workers in the field fully bears out the statement of Keith that it should have the preference over dangerous and uncertain operations for their removal.

Among the several methods of applying the current, preference continues to be given to the intra-uterine applications. The use of vaginal punctures is confined to those cases in which the intra-uterine method is impracticable, as it rarely presents any relative advantage. I have myself reported good results from abdominal puncture in cases of large growths unsuited to other methods. Mere vaginal applications are, however, at times of service, and the possibility of contracting a myoma by external applications even has been amply demonstrated.

Being free from danger in any but reckless hands and certain to be of some service in every suitable case, the electrical treatment of fibroid tumors should be the method of choice as a remedy for these benign growths, whether hemorrhagic or non-hemorrhagic, reserving operative procedures for cases in which electricity is unsuitable. With this careful selection, the best good of the patient is assured and all apparent conflict of opinions avoided.

CONCLUSIONS.

In recapitulation, it may be said that electricity in some one of its methods of application is indicated as a useful remedy in loss of functional tone in the productive organs; in obscure pains in this region; in catarrhal diseases of the pelvic mucous membranes, inclusive of endometritis and its consequence, sterility; in uterine hypertrophies and chronic periuterine inflammations of a non-purulent character; and in interstitial and certain subperitoneal fibroids, whether hemorrhagic or non-hemorrhagic. So much and more has been amply demonstrated and proven, under the fire of a criticism rarely bestowed on any single therapeutic agent. That definite limitations to its use have been proven is also true and almost equally important, yet of this remedy it may be said that, unlike most remedies, the limitations to its usefulness may continue in the present only, for our knowledge of the agent is of so progressive a character that the boundaries of today's information may be left far behind to-morrow.
212 S. Fifteenth street.

MINNESOTA BOARD OF HEALTH.—Dr. Chas. N. Hewitt, Secretary of the State Board of Health, has issued a circular to the different boards of health. He calls attention to the dangers of small pox and cholera which may be distributed by tramps wandering around as harvest hands. He also calls attention to the means of disinfection by use of concentrated alkalies, caustic lime in the form of fresh whitewash and strong soft soap for washing floors, clothing, etc., which is very fatal to microbe growths, and if these are properly used they will add greatly to public safety for this year.

THE PROPRIETY OF OPERATIVE MEASURES IN PELVIC PERITONITIS.

Read before the section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY LEWIS SCHOLLER, M.D.

DES MOINES, IOWA.

Operative interference has become so frequent in pelvic and abdominal troubles that at a casual glance it would seem that nothing had escaped, and that a paper calling attention to any one of the numerous pelvic affections would be superfluous; that all conditions for which operations were advised and practiced were fully understood; that the time for operative interference was definitely settled, and that every community had had an operation or two of this character. A more careful observation, however, will show that neither of these points are settled and without their settlement the status of operative interference is yet a debatable question.

We have arrayed on the one side the conservatives with conservatism carried to timidity. On the other, we have the reckless and amateur operators, of whom the latter are the more dangerous, not alone on account of their inexperience, but in their anxiety to become abdominal surgeons they open abdomens upon the slightest pretext.

Occasionally they may do good, but more frequently harm is the result. Cases of pelvic peritonitis differ in their effects but little from general peritonitis, save in degree and the liability to the formation of abscesses. In this respect they more closely resemble localized abdominal or circumscribed peritonitis. All occur as a result of a cause; none are idiopathic. All are affections, either primarily or secondarily, of the same extensive membrane which lines abdominal and pelvic cavities, and are accompanied by practically the same symptoms and run the same course. When moderate in degree they recover spontaneously, or with little or no treatment, and that of the simplest character, such as rest, diet and simple remedies.

Occasionally, like all other inflammatory disorders, spontaneous cure may result or, technically, resolution may occur; again, the effused lymph may become organized, and after the subsidence of the inflammation important organs may be greatly hindered in the performance of their proper functions on account of the faulty positions which the adhesions cause them to assume. Of the uterus and the ovaries this is especially true: the rectum and bladder also becoming involved. Repeated attacks increase the difficulties already named, and the consequent irritation and pain soon affect the whole nervous system; the patient becomes a wreck frequently in a comparatively short time.

In the class of cases above enumerated there can be little doubt that most intelligent medical men, as well as gynecologists, would advise an operation.

But it is not in this class of cases that difficulties are experienced in determining the course to pursue. The repeated attacks have given abundance of time for observation and reflection, as well as fair opportunity to test every known remedy.

It is in an acute case that the skill of the diagnostician and therapist are put to the crucial test. It is in these cases that the profession are most in need of definite rules of procedure. It is here that the prognosis is most difficult.

The peritoneal investment of a single organ may be involved as a result of a general inflammation of that organ, and this limitation may prevail throughout the course of the disease. Again, the entire pelvic peritoneal investment may be speedily involved. An inflamed uterus, a salpingitis, an ovaritis or a septic condition may prove the initial point of infection. The virulence of the inflammation may be such as to render differential diagnosis difficult or impossible.

If the formation of an abscess or a pus cavity can be made out, the rule to evacuate is imperative, but do we not wait frequently longer than is necessary for the plain indications of purulent deposits? The pointing in the direction of least resistance may not be discoverable until too late. The peritoneal cavity or the alimentary tract may receive the collection while we wait. This has occurred so often that there are none of you but who could recall lamentable instances of its occurrence.

Pyosalpinx, a not infrequent cause of pelvic peritonitis though not so easily discoverable, frequently on account of the small amount of contained pus, is another cause which demands operative measures for the reason that all else is futile. Curetting and packing with gauze the cavity of the uterus is not of itself free from danger, and is certainly not effective. The dislodgment of the pus producing germ cannot be effected in that way, although it may be said to be to a certain extent an operative procedure, yet it is one from which I have failed to secure the desired results.

Inflamed, degenerated and broken down ovaries are beyond restoration; they are not only useless but a source of danger while they remain; they are to a certain extent foreign bodies; no remedies can effect their reorganization or prevent the inflammatory conditions which they excite.

That the patient may survive many attacks of this kind is not to be questioned. The question is, however, as to the advisability of permitting a patient to experience the danger and hazards that are always present in severe cases. The disease in the male analogous to pelvic peritonitis is appendicitis. A patient having experienced one attack is almost certain of a recurrence; some light, others severe in character. As to the danger to life and the inability to determine the gravity of an impending attack, there is no difference of opinion.

Since operations have been more frequently performed, the opportunity for study of the pathology has been greatly enhanced. The terms, typhlitis and perityphlitis, and other unmeaning phrases have been discarded. The diseased organ has been discovered and the remedy applied, which to-day is operative interference, not only during an exacerbation but frequently after an attack has subsided, when apparently all functions have been resumed and to all outward appearances no disease exists.

That skilled surgeons would advise an operation when the presence of disease cannot be demonstrated by objective symptoms, would be one of the unaccountable mysteries of surgery, were it not that pathology and experience have taught us that recurrences are certain and that the interval of quietude offers advantages that both surgeon and patient should not allow to pass.

Early removals of offending organs in pelvic peritonitis are no more dangerous than in appendicitis;

the same immunity is secured, and years of pain, suffering and invalidism are avoided. Without it, localized inflammatory deposits may exist for years, their presence always manifest in some degree at least, susceptible of breaking forth at any time with great violence. If the patients be fortunate enough to escape death they frequently undergo such an amount of suffering that death may almost seem preferable.

I have recently dealt with two cases of this character. For several years repeated inflammations have occurred; neither of them had seen a well day for at least three years; both had been repeatedly confined to the bed,—one for fourteen weeks. At the end of that time she had practically made her usual recovery,—a recovery that was far from complete. Knowing from experience the certainty of recurrence she readily consented to an operation, and while the difficulties of an operation at this time were far greater than they would have been at an earlier date, the recovery was prompt and relief is complete. The second had the same history except none of the attacks had lasted so long. So intense, however, was the last one that life was despaired of at the end of two weeks. Operation was the only alternative; no preparation of the patient could be made for the want of time. The result, however, was all that could be desired. In the earlier years of my practice when operations of this kind were viewed unfavorably by the profession, I have seen many patients lost who would now be saved.

I do not wish to be understood as advocating the propriety of operative interference in all cases. Many cases apparently recover completely and patients continue to enjoy perfect health. Slight pelvic inflammations are not always dangerous, and if they do not become chronic are not seriously inimical to health and comfort.

In these cases the dangers of an operation should not be undergone; other and less hazardous measures will afford equally complete relief.

If you will bear with me for a few moments I will endeavor to formulate a rule or two for time of operations and the class of cases to which they are applicable.

The decision as to the propriety of operative measures and the time when they should be resorted to are frequently beset with greatest difficulties, and the only rule in acute cases that seems to me to apply at all generally is one laid down by some one in intestinal surgery. As soon as it is apparent that other means will be of no avail, the time for operative interference admits of no delay.

In chronic cases, or cases with frequent recurrences, or chronic cases as regards time and acute with regard to symptoms, there are two periods when operation is justifiable. The first, when life is endangered during a recurrence. The second, after the subsidence of an acute exacerbation. This I regard as the preferable period, but unfortunately it cannot be always secured, first for the reason that the acute stage may demand relief; secondly, the patient frequently refuses the tender of relief of this character while the suffering is not intense. Under this head may be included all those cases of encysted collections of pus, gonorrhoeal, or otherwise, tubal collections of whatever character. Diseased and degenerated ovaries, adhesions which give the semblance of tumors by the distortion of the pelvic organs, and

the consequent impairment of their functions, as well as all mental and nervous disorders that are directly traceable to disease of the pelvic organs.

ACCOUCHEMENT FORCÉ IN CERTAIN OBSTETRICAL COMPLICATIONS.

Read before the Section of Obstetrics and Gynecology, at the Forty-fourth Annual Meeting of the American Medical Association.

LEWELLYN ELIOT, A.M., M.D.

—CHURCH TO EASTERN DISPENSARY, PRESIDENT OF THE MEDICAL ASSOCIATION OF THE DISTRICT OF COLUMBIA, ETC., WASHINGTON, D.C.

Accouchement forcé, as we understand it, a labor actively begun and terminated by artificial aid. This assistance may be rendered through mechanical devices, such as Hegar's and other dilators, Barnes' bags, forceps, catheters, sounds, tampons of cotton or wool, sponge tents, or by the hand introduced into the vagina with the fingers acting as dilators. It is our opinion the fingers are the best and safest means of assistance for the reason that the force exerted is active, appreciative and entirely under the control of the operator. The dilation may be rapid or slow, strong enough to produce a laceration of the cervix and body of the uterus, as in the case related by Parrish at the meeting of the American Gynecological Society in 1892, when discussing this subject, where the hand introduced after delivery reached the bifurcation of the aorta but surely this accident must be among the rarest of obstetric novelties. The hand is soft, it appreciates the degrees of dilation effected, it can detect the softening of a rigid os, it can recognize the tearing of a cervix and it can preserve the membranes intact. These advantages can not be claimed by any of the mechanical devices commonly employed; not one of them will afford us any positive information as to the amount of harm that is being done; they only tell us we have dilated sufficiently to require a dilator of a larger size or that we may introduce another and still another alongside of the first; they simply act as any other mechanical device.

The indications which govern us in producing labor or for dilating the os and terminating labor are, placenta prævia, uræmic convulsions, excessive amount of albumen in the urine accompanied by headache, dimness of vision, anasarca, general or limited, and other symptoms leading us to fear convulsions, uterine inertia, rigid os, escape of waters with inefficient pains, spasmodic contraction of the uterus. Any one of these conditions demands our assistance, but how many of us go to a case of obstetrics with forceps and all other mechanical apparatus pertaining to the correct practice of an art; indeed, how many of us are the possessors of such appliances? For one, I plead guilty to the charge of not possessing all of them. When called to a case of rigid os, or where the pains following the premature discharge of the waters are slow, useless, inefficient, why should we send for any artificial dilator when we have with us the safest and best dilator to be found, in the fingers? Are we to allow a placenta prævia case to pass slowly but surely from our hands to a certain death if not relieved, simply because our teachers of obstetrics and our textbooks do not counsel the course I advocate? How many sorrows have been scattered, how many constitutions have been shattered, how many happy homes broken up, how many useful and talented women have gone to their untimely graves through this blind following

the letter and the law of the textbooks, this ideal "follow my leader?" I am making an assault upon no teacher, upon no writer of either textbook or journal article, but it appears singularly singular that so few of our modern obstetric textbook writers mention accouchement forcé in any connection.

Charpentier says it should never be performed unless all other means have failed. Winckel says it is rarely necessary. Lust says it is next to doing nothing and is responsible for many deaths, while Müller says the maternal mortality is 30 per cent. greater than the dilation by tampon or kolpnynter. King, Parvin, Galabin, Reynolds and Davis do not mention the subject. Consider for a moment the statistics of Nordman, who gives a percentage of fetal mortality of 5.8 in cases where version and immediate extraction are performed; 16.6 per cent. following the employment of the tampon and kolpnynter; while version and slow extraction show the death of every child so delivered. In this day of scientific and exact methods in the obstetric art we must consider the claims of the child to life as well as those of the mother. Few men do a craniotomy on the living child, and as few wait until the child is dead before taking active measures so we are forced to adopt the plan of treatment which gives the best results, no matter how ancient the method may be or what may be our convictions.

It will be urged that rapid delivery will be followed by postpartum hemorrhage, shock, uterine inertia or laceration of the cervix, but we have means of checking hemorrhage in cold or hot applications; intra-uterine irrigations with vinegar; friction, ergot, electricity and the tamponade of the uterus; for the uterine inertia nothing will cause the organ to react sooner than the presence of a foreign body, and the uterine tampon of iodoform or other medicated gauze is the most harmless foreign body we possess; for the shock, we possess the same remedies we have for shock of any kind; so far as the laceration of the cervix is concerned, it will be a difficult question to decide, whether the laceration was caused by the artificial dilation or whether it depended wholly upon the passage of the child and was not one of the generally attending accidents of labor. For my part these objections do not deter me from employing this method. In looking over my case records I find this method by the fingers to have been employed in cases in which uremic symptoms were alarming, of rigid os and of placenta previa, and my experience is embraced in part in the following brief histories:

Statistics in cases of placenta previa are always misleading for the reason that many men will include all cases of placental attachment, marginalis as well as centralis; a partial implantation will usually prove an easy matter but the centralis will be attended by the more serious results.

Case 1.—M. W., white, aged 34 years, was delivered of her third child in January 1885. She complained much of headache, dimness of vision, edema of face, body and lower limbs, urine highly albuminous, abdomen very large; had a laceration of the cervix and partial rupture of the perineum at a former labor. Was given several doses of the compound jalap powder, in the hope of relieving her. With free actions from the bowels her condition became more comfortable. Labor pains came on at three o'clock in the evening. At twelve o'clock the os had dilated very little, vertex presenting; was now given hydrate of chloral and bromide of potash. At one o'clock introduced two fingers into the os and separated them to their fullest extent, then three fingers, then four fingers and separated. Pains were

strong; the head was pushing down rapidly and at ten minutes past two the child was born. The placenta was expressed without difficulty. No hemorrhage, uterus contracted well under ergot. Child affected by the chloral, but revived during the night. Mother made a good recovery.

Case 2.—M. M., white, aged 31 years. In fifth confinement uremic symptoms. Pains not sufficient to dilate os. Chloral hydrate and bromide of potash did not hasten labor. Head presenting. Gave chloroform; introduced hand into the vagina and dilated os with the fingers; applied forceps and delivered her of live male child in one hour from the introduction of the fingers. Placenta expressed; no hemorrhage requiring attention; ergot given. Recovery complete.

Case 3.—M. G., white, aged 35 years. In her seventh confinement; cervix and perineum lacerated in a former labor. She was delivered in a very filthy bed and filthy room. Pains came on at twelve o'clock on the evening of the 26th of May. Os rigid, pains strong and frequent, the waters were not discharged. Dilatation to admit two fingers, fingers separated; three fingers introduced, then four fingers, bag of waters formed but kept intact. After such manipulations at intervals, for one hour and a half, the child was delivered naturally at half past three on the evening of the 9th. Child strong and healthy. Placenta came away with little hemorrhage. Recovery complete.

Case 4.—R. M., white, aged 36 years. In her fourth pregnancy. Had irregular hemorrhages for about three months, oozing and passing of clots; when early in her seventh month she had a severe hemorrhage. Vertex presenting. Cervical canal and vagina had been packed with iodoform gauze by her physician. Called at three o'clock in the morning, and notwithstanding the fact that the hemorrhage had been checked, I advised the immediate emptying of the uterus. Chloroform was administered, the gauze removed, the tissues found soft. Dilated with the fingers; applied forceps and delivered; the hemorrhage was quite free, the uterus emptied at once, irrigated and then packed with iodoform gauze and ergot given. The child was alive; the mother recovered in the usual time. Time required for the manipulations forty minutes. Placenta centralis.

Case 5.—F. S., white, aged 31 years. In her first pregnancy. Had hemorrhage during the fifth; in the sixth month she had a very free one. She was tamponed by her physician and the bleeding had ceased when I arrived at the house. Her pulse was thready and feeble; her face showed the loss of blood, respiration sighing and all the symptoms of collapse were present. Her condition was such that I did not think interference at that time justifiable and advised lowering the head of the bed, absolute quiet and a change of the tampons during the evening; should hemorrhage be present to dilate and deliver. All went well until one week after, when she got out of bed to attend to some household duties; the bleeding started afresh to be checked by tampons. It again started in the early morning with intense labor pains and a rapid delivery of the child. The hemorrhage was appalling, cold, ergot by the mouth and hypodermically, friction, all in turn failed to check the bleeding. Arriving about three-quarters of an hour after the delivery I packed ice in the uterus, used friction upon the hand within the uterus through the abdominal wall, irrigated with vinegar and these means failing the uterus was packed with roller bandage, no gauze being at hand. The hemorrhage was immediately stopped, but the loss of blood had been so great that she could not rally from the shock and died three hours after the delivery. The child was still-born. Placenta centralis.

Looking back now to this case, I think I should have delivered this woman at the time of my first visit and not let her run any further risk, but the outlook was so unfavorable I hesitated and the time for action passed. Should such a case again present, my course would be rapid dilatation and immediate delivery.

In irrigating these cases, we may use the solution of bichloride of mercury, carbolic acid or any other medication which individual preference may suggest; for my part I employ a solution of Tyre's antiseptic powder, which consists of borax, alum, carbolic acid, glycerin, and the active principles of thyme, mentha, gaultheria, and eucalyptus scientifically combined.

1106 P street, Washington, D. C.

COCAINE: ITS USES IN GYNECOLOGY.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY WM. H. HUMISTON, M.D.

FELLOW BRITISH GYNECOLOGICAL SOCIETY; CONSULTING GYNECOLOGIST TO CITY HOSPITAL, CLEVELAND, OHIO.

Having now had five years' experience in the use of cocaine in gynecological operations, I feel better prepared to eulogize its merits now than I could do two years ago, when I first brought this subject to the notice of the profession at the Washington meeting. I stated at this time that the only annoying symptom that frequently arose was the shortness of breath, and the anxiety connected with it—this I have been able to obviate by the use of strychnia or tincture of nux vom.; one-thirtieth grain of the former, or fifteen minims of the latter, administered with one-half ounce of whisky thirty minutes before operation.

I do the following operations with no other anæsthetic than cocaine, viz.: dilating, curetting, trachelorrhaphy, anterior and posterior, colporrhaphy, and perineorrhaphy. Frequently making two of these operations at one sitting. In dilating and curetting primipare, I resort to cocaine in preference to chloroform or ether; and the pain produced is but slight, and the convalescence is uninterrupted and rapid.

The essentials of this method are: 1. Asepsis. 2. Pure cocaine. 3. Quantity, and how used.

1. The parts to be operated upon should be thoroughly cleansed, and all instruments used *sterilized*, and especially the hypodermic syringe and needle.

2. It is essential that a reliable preparation of cocaine be used, and I rely upon Squibb's or Merck's. I prepare them in two strengths—a four and a ten per cent. solution; the former for hypodermic use, and the latter for intra-uterine injection preceding curetting. I prepare but small quantities at a time, only one drachm of each strength made from sterilized water, to which is added one drop of pure carbolic acid to prevent the solution changing or depositing flaky particles.

3. The quantity of cocaine used for each sitting is from three-fourths to two grains; where but one operation is done I use from one-half to one grain. For curetting I steady the uterus with a tenaculum, and with hypodermic syringe inject the posterior lip with two or three minims of the four per cent. solution. I then take a firm hold of the posterior lip with the bullet forceps, which is painless, and then inject as much more as near the internal os as I can. If necessary to dilate, I do so, until the intra-uterine syringe will pass to the fundus of the uterus, when I throw in eight or ten minims of a ten per cent. solution. I hold my syringe in place a minute to allow the cocaine to be retained, and anæsthetize the mucous membrane as much as possible. After waiting two minutes I proceed to thoroughly curette the whole cavity, followed with a free washing by a double catheter. A few patients complain of some pain, but not enough to desire chloroform or ether, and a great many state that it was absolutely painless. In making trachelorrhaphy, single or double, but one surface is injected at a time, and after one minute you can proceed to freshen the portion mapped out without any pain. I have frequently freshened the whole surface of a double laceration without the patient experiencing the slightest pain. The average amount of the four per cent. solution

used in a double operation is twenty minims. I use a very fine hypodermic needle, and do not inject deeply unless I wish to cut out a large V-shaped portion of the cervix.

4. In colporrhaphy I inject a four per cent. solution in a circle surrounding the portion of the mucous membrane to be removed, and this anæsthetizes the whole portion, and denudation can be done with but little bleeding, and no pain—amount used twenty to thirty minims. In perineorrhaphy I generally make the split flap operation. I make but one puncture with the hypodermic needle, and this in the median line at the junction of the skin and mucous membrane at the vulval opening—inject gradually to a depth of one inch, then carefully withdraw the needle until you are near the point of entrance, when you change the direction of the needle and inject the right vulval edge to the height you wish to restore the perineum, and in a like manner the left. The sear will readily show from what point the rupture took place and it is best to restore to the full extent. Within two minutes after thus injecting twenty to thirty minims of a four per cent. solution, you can proceed to operate without pain. Before inserting the sutures it is well to inject a few minims more along the cutaneous border.

I will now briefly refer to a few cases:

Mrs. H., age 34, married at 19 years of age, menses regular, not painful; has had four children, youngest four years old. Had inflammatory rheumatism when eleven years old, and again three years ago; attacks were severe, but does not think had any heart complications until last attack. Patient believes that injuries to cervix and perineum occurred at birth of last child, as she had a prolonged getting up, and has not been well since.

When I was called to this patient I found her in bed, very weak and anemic, pulse 118, temperature 100, with frequent attacks of sinking spells, cold hands and feet, and extremely nervous. On examination found heart enlarged, and murmurs at both apex and base of heart. On vaginal examination found perineum torn to sphincter ani, uterus retroverted, enlarged and tender, cervix lacerated, swollen, eroded. Ovaries enlarged and very sensitive to pressure. This case not only required local treatment, but operative measure. I felt chloroform and ether was out of the question as the heart was so diseased.

After a few weeks of local treatment with general systemic measures, she was so far improved that I was able to move her to my private hospital for operation. One-half hour before curetting I gave her fifteen minims tincture of nux vomica in one half ounce of whisky. I made use of the cocaine as described above, using one grain together of the four and ten per cent. solution; I proceeded to curette, and to my surprise she had no shortness of breath, or anxiety, and no pain. The pulse was less rapid, and of more force under the effect of the nux vomica and whisky.

This patient was in such reduced condition from her long illness and menorrhagia, that her power of endurance or ability to suffer pain was *nil*, and she was morally certain before the operation that she could not endure it without ether or chloroform, yet to my surprise she did better than any case I had before curetted.

At intervals of ten or twelve days I repaired the cervix and perineum, with the same happy effect from the cocaine. The operations were all successful, and she is now able to do light housework and be comfortable.

Believing that the administration of the nux vomica was responsible for the freedom from the anxious breathing that cocaine is so apt to produce, I have given it since to every patient operated upon, and I esteem it highly, and trust it will gain your confidence after repeated trials.

My last reference will be to a case of chronic lung trouble, that had uterine disease and required operative measures, but an eminent specialist of Pittsburgh refused to operate owing to the serious condition of her lungs, precluding the administration of chloroform or ether. She was sent to my hospital, and I did currying and trachelorrhaphy without the slightest pain or difficulty by the use of cocaine after the above method.

Her cough and general condition improved, and she was able to remain in this climate during the entire winter without taking cold or becoming worse. For four years her winters had been spent in Florida or Colorado.

There are no unpleasant after effects from the use of cocaine aside from a slight headache in some cases. No vomiting or shock, and convalescence is rapid.

I could multiply these cases by the score, as I am operating almost daily without having any untoward symptoms, and I desire to thoroughly impress my brother gynecologists with the desirability of cocaine as an anæsthetic in all minor gynecological operations.

A SUCCESSFUL CASE OF CÆSAREAN SECTION.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY GILES S. MITCHELL, A.M., M.D.

PROFESSOR OF OBSTETRICS IN CINCINNATI COLLEGE OF MEDICINE AND SURGERY.

Until the last decade the Cæsaean section occupied a doubtful place between conservative and sacrificial midwifery. Puzos, the distinguished author and obstetrician, writing in 1875 concerning Cæsaean section makes the following statement: "This operation has cost the lives of all the unhappy, ignorant women who have undergone it in Paris since the beginning of this century." And he adds, "it is still practiced." Even Robert Barnes, whose name is a household word with the medical profession, in the last edition of his work on Obstetric Operations, uses the following language in speaking of it: "It is resorted to with a feeling akin to despair for the fate of the mother, which is scarcely tempered by the hope of rescuing the child. It is looked upon by the great majority of obstetricians as the last desperate resource, as the most forcible example of that kind of surgery which John Hunter regarded as the reproach of surgeons, being a confession that their art was baffled." These quotations are ample apology for the brief recital of a successful case:

Patient, Mrs. H. Irish, aged 24, primipara, rather delicate and of a highly nervous temperament. Saw her for the first time late in the afternoon of April 24, 1893. She informed me that she had reached the end of her gestation, and from the pain she was having thought she was in labor. Date of last menstruation, July 10, 1892. On making digital examination I recognized a hard solid tumor extending from above the sacral promontory, down and filling up the major portion of the sacral concavity. Pelvic diameters of outlet normal. Conjugate of middle strait about 2½ inches, conjugate of brim 1½ inches. All of the uterus was above the pelvic inlet and the os undilated was pushed forward and felt above the pubic symphysis. Recognizing that a formidable

surgical operation would be necessary in order to accomplish delivery, and in view of bad hygienic surroundings, I requested that she go to a hospital. This she absolutely refused to do. The pains being feeble and the os not dilated, I concluded to do nothing until morning, save irrigate the vagina with a bichloride solution 1:4000, and wash out the lower bowel with warm water and glycerine. Early on the morning of the 15th dilatation was sufficiently advanced to readily admit the index finger. Vertex presentation was diagnosed. The position being the right occipito anterior. The pains being now severe and the amniotic sac having ruptured, it was deemed advisable to wait no longer. So after consultation with Dr. Chas. A. L. Reed, the child being alive, it was deemed wisest, best and safest to deliver by means of the Cæsaean section. Promptly at 8:00 a.m., April 15, about fourteen hours from the time I first saw her, I began the operation, assisted by Dr. Chas. A. L. Reed, and in the presence of Dr. Robert B. Mitchell and Dr. Edgar Reed and the nurse, Miss Schwank. Chloroform was anæsthetic employed. Patient's temperature was 101½, pulse 114. The abdominal incision was eight inches in length, two-thirds of it being above the umbilicus. There was very little bleeding from the abdominal parietes. As soon as the uterus was exposed a loop of rubber tubing was slipped over the fundus and brought down to the neck. The uterus was then quickly opened, the incision being about six inches in length, through the fundal and middle zones. Delivery was speedily accomplished by means of the feet. The child, a male weighing 7½ pounds, was asphyxiated, but Dr. Reed soon succeeded in resuscitating it. Only eight minutes elapsed from the beginning of the operation until the child was born. There was considerable bleeding from the uterine sinuses, but it was readily controlled by tightening the elastic ligature around the cervix. The placenta was attached high up posteriorly, and was removed shortly after the child without difficulty. After waiting a short time for the uterus to contract, the wound in it was closed by means of a Lembert-Czerny continuous silk suture through the peritoneum only. The equivalent of thirteen interrupted sutures was passed. The abdominal walls were then carefully united by means of eight interrupted silkworm gut sutures. Neither the uterus nor the abdominal cavity were washed out, nor was there a drainage tube placed in the cervix. The external dressing consisted of iodoform gauze and cotton held in place by strips of rubber adhesive plaster. The stitches were removed on the seventh day, union having taken place by first intention along the entire wound. Not a suspicion of pus was manifest at any point. On the tenth day the patient was, from a surgical standpoint, well. The following is the record kept by the nurse:

April 15, 8:00 p.m. Resting quietly. Vomited once two ounces clear fluid. Lochia normal. Passed 8 ounces urine. Has taken nothing, save small quantities of hot water.

April 16. Patient passed a comfortable night. Lochia normal. Took during the day a tablespoonful of chicken consommé every two hours. Morning temperature 99.6°, pulse 100; evening temperature 100.2°, pulse 120.

April 17. Patient slept several hours; complained of pain in lower part of bowels. Lochia normal. Morning temperature 101°, pulse 100. Took chicken consommé. Passed normal quantity of urine.

April 18. Rested well; slept several hours. Lochia and urine normal. Morning temperature 100.8°, pulse 84; evening temperature 102°, pulse 90. Had small stool.

April 19. Very restless night. Patient delirious greater part of the day. Morning temperature 101°, pulse 88; evening temperature 102.2°, pulse 90. $\frac{1}{2}$ grain doses of calomel were given every half hour during the day until a grain and a half had been taken, when the bowels were freely moved.

April 20. Patient had a restless night. Morning temperature 100.4°, pulse 98; evening temperature 99.8°, pulse 76. Slept an hour at a time twice during the day; rested easily, complained of no pain. Bowels moved twice very freely. Enjoyed her food, consisting of chicken consomme and milk toast.

April 21. Patient slept greater part of the night. Morning temperature 99.8°, pulse 80; evening temperature 100.8°, pulse 88. Slept most of the day.

April 22. Passed a very comfortable night; slept well. Stitches removed. Takes milk, brandy and beef tea freely, and ate a lamb chop. Morning temperature 99°, pulse 82; evening temperature 99.6°, pulse 88.

April 23. Patient rested well, but had a slight chill during the night. Morning temperature 101.6°, pulse 92; evening temperature 100°, pulse 88.

April 24. Patient rested well. Morning temperature 98.6°, pulse 88; evening temperature 99.6°, pulse 82. Appetite excellent; no pain.

April 25. Morning temperature 99.4°, pulse 82; evening temperature 99.6°, pulse 100. Patient slept all night. Lochia scant; urine normal. Bowels moved by injection.

April 26. Patient slept most of the night. Morning temperature 99°, pulse 80; evening temperature 99°, pulse 84. Patient says that she is well.

April 27. Patient passed a comfortable night; appetite good, lochia scant, bowels moved slightly. Morning temperature 99°, pulse 84; evening temperature 99°, pulse 83.

Authors make the statement that two-thirds of the abdominal incision should be below and one-third above the umbilicus. In the case reported this order was reversed. The same authorities advocate two rows of sutures in closing the uterine wound, one set of deep sutures penetrating almost the entire thickness of the womb, and a superficial set. In the case reported I employed a continuous suture, and embraced in it only the peritoneal covering of the uterus. I have long contended that deep sutures in the uterus were not necessary, and often are a source of danger. The peritoneal covering of the uterus at the end of gestation is very greatly hypertrophied, and is so firmly adherent to the muscular tissue in the upper two-thirds of that organ that it is impossible to separate them without tearing one or the other. This intimate relationship, together with the peculiar shape of the womb, and the rhythmical contractions and retractions constantly going on, make it unnecessary to do other than unite the peritoneal covering. While I claim great advantage for my mode of suturing, I am not ready to acknowledge that it was the most important factor in leading the case to a successful termination. I saw the case early, and operated promptly and quickly, the operation being over and the patient in bed in thirty minutes from time operation was begun. No damage had been done to the soft parts in vain attempts to deliver by the forceps. Labor had not only begun, but considerable dilatation was present. In addition, I did a simple Cesarean section. The tubes and ovaries were not molested. All of which contributed toward a fortunate termination of the case. I believe, however, that ligation of the tubes adds very little to the danger, and in future, should I be called upon to make the operation, will render the patient sterile by that procedure. The operation was rendered as nearly aseptic as possible. This was difficult, as the family cooked, ate, slept and lived in one room.

The chief interest and importance of Cesarean section is in the grave responsibility resting upon

the accoucheur, when he is called upon to decide whether he will save the mother and sacrifice the child, or, by increasing the danger to the mother, hope to rescue both. It seems to me that in the light of modern surgery, with its improved methods and with the brilliant results from the operation obtained during the past decade by clever men all over the world, that the conscientious obstetrician has nothing to embarrass him in deciding between embryotomy and Cesarean section.

Dr. Murdock Cameron, of Glasgow, from 1889 to 1891 made ten Cesarean sections, with a mortality of one mother and one child. Such gratifying results ought certainly to convince us that embryotomy on a live child has no right longer to be considered a justifiable obstetric procedure.

Dr. CHAS. P. NOBLE of Philadelphia: No subject of greater importance could be brought before the Section than how to deal with a case of pregnancy with a full term fœtus which can be delivered *per via naturales* without mutilating the child. Recently we had introduced in this country an operation which bids fair to supplant both the Porro operation and Cesarean section. He had never done a Porro, but had done two Cesarean sections, both of which recovered, and had charge of two other cases which recovered. Within the past year he had operated by symphyseotomy with success, and quite recently had assisted another gentleman in delivering a woman by symphyseotomy. He believes we can deliver practically every woman by symphyseotomy with a conjugate diameter of two and three-quarter inches and upwards, without danger to the mother, provided the operation is done in the right way.

Dr. JOSEPH PRICE of Philadelphia, said not a little confusion had arisen in regard to the respective merits of the Porro operation and Cesarean section. The two operations were done for entirely different conditions. He had done six Porro operations, all for tumors. Dr. Robert P. Harris of Philadelphia, writes Dr. Price, "that the conservative Cesarean operation has been performed seventy-five times in the United States, the Porro-Cesarean twenty-nine times, and symphyseotomy eighteen times; with two also in Canada. There have been sixteen Sanger operations and fifteen Porros since March 1, 1891, with one death after the former, and three after the latter. Fatal deaths respectively, two (one at six months); and five, (four still born). Since July 12th, 1891, Philadelphia operators have had ten Porro cases, and New York four."

Dr. MITCHELL, in closing, said in the case reported the deformity was due to a large tumor extending from above the promontory of the sacrum and filling out almost the entire concavity of the sacrum. The conjugate diameter of the middle strait was two and one-half inches, while at the inlet of the pelvis it was not more than an inch and a half; consequently he thought the case was not a suitable one for symphyseotomy.

SELECTIONS.

The Berlin Sewage and its Lesson.—The *Cosmopolitan* for July contains an interesting article by Mr. Poulteney Bigelow on "How to Make a City Cholera Proof." We extract the following:

"In the summer of 1887 I was taken over the great sewage farms about six miles from Berlin. I was accompanied by the bacteriologist, Dr. Koch, who let fall the remark that, in his opinion, Berlin was proof against an epidemic, owing to

the manner in which her sewage was carried away and rendered innocuous.

The great cholera epidemic came and paralyzed the commerce of most of the seaport towns of Europe, devastated Russia pitilessly, and left the great city of Hamburg more impoverished than when the troops of Napoleon evacuated it.

Berlin looked upon the progress of the plague with equanimity, although she is on the highway between Hamburg and Russia and daily exposed to an attack because she lies upon a river connected by means of canal, not only with the waters of Hamburg and Russia, but of an infected port on the Baltic, Stettin. Her hospitals accepted, as a matter of course, the isolated cases of cholera that occurred in her neighborhood, but there was at no time anything approaching to an epidemic within her walls.

The experiment made by Berlin in utilizing her sewage by making it enrich the sandy soil of the neighborhood has proved so successful, is so simple, so inexpensive and so well suited to the needs of New York that a few words of description may not prove uninteresting.

The present system of cleansing Berlin has been tested by nearly twenty years of thorough experience.

Berlin, for scavenging purposes, is divided into districts. A huge cesspool in each, collects all the sewage in that particular district, and this sewage, by means of powerful engines, is uninterruptedly pumped off, far out of the city, on to land specially prepared for this purpose.

I visited the Blankenburg farm of 2,700 acres. The road along which we walked was deep with sand. On either side of us, however, were fields rich with a most luxurious growth, which, but for the irrigation to which they are subjected, would be as fruitless as the road on which we walked.

There were, in the official year 1885, some 10,000 acres under irrigation for a variety of purposes, including experimental agricultural purposes, nurseries and flower raising. The staple crops, however, were summer and winter rape, mustard, hemp, winter and summer wheat, winter and summer rye, oats, Indian corn, barley, buckwheat, peas, beans, clover, grasses, potatoes, beets, cabbage, chicory and turnips. Cereals alone took up nearly 4,000 acres.

In its original condition, that is to say, before the city of Berlin adopted the present method of cleansing itself, this land was worth \$182 per acre. As soon, however, as sewage is applied to it, the value rises to over \$400 per acre.

The dreariest stretches of sandy Long Island are picturesque, if not luxuriant, in comparison with the country about the German capital. Yet on this soil are now being raised crops that would astonish an Iowa State fair.

Learned lights of the German scientific world had gravely told their hearers that for one year, two years, possibly three years, the system might work; but that the time must speedily be when the soil would contain so much sewage matter as to not only make vegetable growth impossible, but to poison the air and water of the whole surrounding country. But the managers of the sewage farms have found that they have no difficulty in adapting their crops to the strength of the soil. In other words, they can exhaust as fast as the city can restore.

Another great source of alarm was lest the drainage from the irrigated fields should poison the waters of the neighborhood. So serious was this feeling among all classes that a law was passed making it punishable, by a fine, for any one to drink from the waterways near any of the sewage farms.

Dr. Koeh, the authority on bacilli and disease germs, told us, on the spot, that before disease germs could propagate themselves in Berlin they were hurried off on to this soil, which is completely destructive to bacilli. The six hours

that intervene between bacilli entering the drains of a Berlin house and reaching the ditches of the sewage fields, are not enough to give the disease a start.

The water offered me had entered the sewers of Berlin only six hours before. The only cleaning it had received was in percolating from the irrigated field into the ditch that surrounded it. So effective, however, is this, that my drink was not only as clear as pure spring water, but the taste was as though it had been distilled—a taste familiar on shipboard. And not only was this water free from odor, but the air on and about the irrigated fields was not tainted to a point that could be called offensive.

The sewage is so largely cleansed by the mere passage through six miles of pipe that, after it has been a short time upon a field, the odor is hardly noticeable. The complaints from neighboring farmers, which at first threatened to wreck the enterprise, have quite ceased.

So great is the demand for "sewage vegetables" that the market people are clamoring to have a special section reserved for this growth alone alleging that in that way they can get higher prices for these particular vegetables.

For the twelve months between March, 1885, and April, 1886, the cost of cultivating 9,194 acres was \$134,778, while the income from the same was about \$271,000, being a profit of over \$136,000, or about \$32.50 for each acre. This profit is calculated without reference to the general and official expenses and interest on capital. Counting, however, all possible charges, the profit still amounts to an average of \$18.50 to the acre.

We all know that more danger to the public health arises from the sewers than from any other cause, and that therefore scavenging as a profession must be a dangerous one. But the system under which Berlin purifies herself is happily freed from the ill effects attending all others.

The several estates making up the total area of the sewage farms were supporting last year 33,749 souls. Out of this number there were 237 cases of illness, the causes of which are interesting to note.

To apply the lesson of Berlin to our requirements it would be necessary:

First, To acquire enough land between Whitestone and Coney Island to enable the city to lay out fields suitable for irrigation, and enough of them to meet the anticipated increase in the population.

Second, The sewage of New York island, instead of being turned into the surrounding waters, would then be collected at a dozen points on the east side of the town, between the Harlem and the Battery.

Third, From these points of reception it would be pumped off, night and day, by means of powerful engines, through suitable pipes, out on to the city farms. None of these farms need be more than ten miles from its particular pumping station. One pipe line, for instance, might lead from the foot of Fulton street out in the Flatbush direction. Another, from the foot of Tenth street, could work the Jamaica neighborhood. Several pipe lines could cross the East river at Blackwell's island and enrich the Flushing neighborhood, which now pays such heavy taxes for manure.

The Administration and Dosage of Pancreatic Extract and Trypsin.—Recent improvements in the manufacture of pancreatic extract and trypsin have placed in the hands of the clinician preparations of digestive ferments of high digestive power and of such uniform and standard quality as to entitle them to a position among reliable therapeutic agents. It is now understood that all pharmaceutical preparations, purporting to contain pancreatic ferments, must be subject to well-known laboratory tests of digestive activity, just as in the parallel case of pepsin, and those which are deficient or altogether wanting in this respect, are rejected. In other words, if a preparation alleged to contain pancreatic ferments, does not possess digestive activity sufficient to convert proteids into peptones, starch into maltose or dextrose, emulsify fat, or curdle milk, or possesses these qualities to an insignificant degree, it is to be judged worthless as a digestive agent. If it be claimed that such pharmaceutical preparations are still valuable on account of their

carminative and stimulant qualities from spice or alcohol which may be present, the rejoinder would be that there can be no objection to the administration of such adjuvants if the case require them, but if a digestive ferment be demanded, and pancreatic extract be desired, then it is incumbent upon the prescriber to see that he gets a physiologically active preparation, and that he does not allow himself to be put off simply by a name.

As now furnished in the form of an impalpable, dry powder, which possesses, and retains permanently a high digestive equivalent, it certainly would seem that the requirements of clinical medicine of pharmacy, in this direction, are fully satisfied and that other preparations are unnecessary. Glycerin is the only solvent which enables us to administer or apply the digestive ferments in a liquid form without loss of activity or liability to precipitation. Since the acid media in which pepsin is alone active renders pancreatic ferments inert, and the neutral or alkaline media required by the latter precipitates the former, it would certainly appear illogical and unphysiological to administer pharmaceutical compounds of these two classes of ferments. In such cases, one or the other is useless and wasted. In order to obtain the best effect from the pancreatic extract, it is given in combination with sodium bicarbonate, usually in the form of compressed tablet, or in a gelatin capsule. The glycerin solution has special advantages for topical applications in diphtheria and for surgical dressings.

The proper time for the administration of pancreatic extract or trypsin, is just before a meal or about two hours afterwards; just before eating because it may pass into the intestine before the acid gastric juice has commenced to be secreted, or later, when gastric digestion is complete and the chyme is passing into the duodenum and intestinal digestion is in progress. In cases of apesia, or achlorhydria, and in conditions of fever where gastric digestion is suspended, the pancreatic preparation may be given with the food. The dose of the active preparation now furnished under the name of pancreatic extract is from two to five grains, usually combined with twice as much or even more of bicarbonate of sodium. Some reliable forms of combination, such as that with ox gall, are also to be obtained from the leading manufacturers of preparations of the digestive ferments. Since alcohol and some metallic salts precipitate the digestive principles from their solutions, it is advisable not to administer such remedies coincidently with the ferments; especially is the old form of wines or elixirs of these ferments objectionable. The physiological fact that digestion differs from fermentation, is illustrated by the action of creosote, which stops fermentation but does not interrupt the process of digestion or the action of the digestive ferments. Creosote, or guaiacol, therefore, is a useful adjuvant to the digestive ferments where there is an excess of flatulence due to acetous fermentation, or in so-called "windy dyspepsia." Although the dosage above mentioned is the quantity ordinarily prescribed, much larger doses may be given if thought desirable, since, unlike many of our other remedies, the digestive ferments have no toxic action and in excess have not been known to cause irritation. There is a theoretical danger from prolonged administration, that the normal secreting glandular function may be superseded and artificial digestion become a permanent necessity. Unfortunately, in many of the cases in which a resort to the use of pancreatic extract is required, the functional activity of the glandular apparatus has already been more or less permanently impaired, and in such cases the systematic administration of the digestive ferments affords the only means of living in comparative comfort, and of relieving them of their thralldom to the demon, dyspepsia. Where there is emaciation due to

impaired assimilation of fats, pancreatic extract should be given in sufficient doses, guarded by sodium bicarbonate, to bring about a disappearance of fat from the stools, and it should be continued until this symptom disappears.

Clinically speaking, the pancreatic ferments, or trypsin (which is a purified pancreatic extract), have been found especially useful in the digestion of milk proteins, trypsin possessing a marked power of digesting casein. This has been utilized in pre-digesting or peptonizing the milk for infants and invalids with delicate stomachs. As this process softens the curd, and approximates cow's milk more closely to mother's milk, this expedient has proved (in connection with sterilization of the food), of inestimable advantage to bottle fed babies and badly nourished neurasthenic patients of larger growth. The process has been very much simplified for domestic use by the manufacturers providing the proper quantity of extract and soda, in hermetically sealed tubes, each containing sufficient ferment to peptonize a given quantity of milk. The only manipulation required is to warm the milk to a blood heat, mix with it the contents of one of the tubes; a few minutes' contact only are required to sufficiently digest the casein, when the further digestion is at once arrested by bringing the milk to the boiling point, which destroys the ferment. In the case of infants, the powder may be added to the bottle just before feeding, or administered separately, dissolved in water, immediately afterward. For making "humanized" milk from cow's milk, a special peptogenic milk powder has been prepared by the manufacturers, which contains sugar of milk and other principles required to make cow's milk a proper substitute for breast milk in the diet of infancy.

Some acceptable articles of nutrition for the sick may be made with the aid of pancreatic extract. The diastatic action may be utilized by adding the extract to various starchy foods, such as gruel; always being careful not to impair the digestive activity by excessive heat (over 130° being the limit). The late Dr. N. A. Randolph, in an article entitled "The Dietetic Factor in the Treatment of Angina Pectoris," after commenting upon a case in which a paroxysm was brought on by slight gastric irritation, with inability to retain even the lightest and simplest foods, reported that he had successfully met the emergency by the use of pancreatic extract. He prepared pancreatized stewed oysters and milk toast, and suggested that this expedient might be extended to other articles of diet with much advantage in similar cases of gastric hyperæsthesia, so as to enlarge the rather scanty bill of fare of such patients.

The very interesting and possibly useful discovery was made by Randolph, while studying the absorption of remedial agents by the skin, that the resistance of the epiderm and the more important obstacle afforded by the sebaceous secretion might be overcome by the application of a solution of pancreatic extract. This is best given in his own words: "A very simple and efficacious method which we have devised for removing these obstacles consists in the addition of a proteolytic ferment to the solution of the drug used. Thus trypsin (prepared by Kuhne's method), is added to a strong solution of (e.g.) morphia. Absorbent cotton is saturated with the mixture, placed upon the skin and covered with waterproof plaster. The natural warmth of the part induces activity of the ferment and the consequent solution of the epiderm, narcosis supervening in from one to two hours. This method, when applied under the supervision of the physician, affords one advantage over ordinary modes of medication, namely: that when the desired therapeutic effect is obtained, the further absorption of the drug may be prevented by at once removing the external application."¹ It does not appear that this ingenious suggestion has as yet been actually employed in clinical therapeutics; but it would seem of great advantage in local neuralgia; and painful tumors, even though it be not necessary to push to its full physiological effect the drug with which it is associated. Thus in the case of morphia or codeine, the anodyne action might be thus obtained at the point where it is most needed, without the narcotic or secondary effects from the usual or hypodermic method of administration.

Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 2, 1893.

THE AMERICAN MEDICAL ASSOCIATION.

An extract from the valedictory of the former editor of this JOURNAL has had a wide circulation in certain not over-friendly publications. The valedictory mentioned contained certain well meant but erroneous statements, which, when published by themselves were calculated to damage the JOURNAL in its business interests and the ASSOCIATION. If the ASSOCIATION critics had reproduced the *whole* article, we would not now need to explain. The article was written before the returns were received from the Milwaukee meeting.

At that meeting there was an increase in membership of 273, and in the last month, the membership by application has brought the increase up to 300.

There has never been a time when the JOURNAL had so large a bona fide mail list, and there has never been a moment when there was not money in the treasury; more than sufficient to meet any possible contingency. There have been added eight pages of reading matter, and the outlook for the publication has never been brighter than at present.

We have maintained silence on this subject up to this time, as we dislike to make public mention of the business affairs of this office, but as longer silence might be misconstrued, both within and without the ASSOCIATION, we have thought proper to state the facts.

The ASSOCIATION door is always open for new members by application, and they are welcomed because we strengthen the ASSOCIATION with every new addition, and so far as the JOURNAL may be able, it will continue to urge every member of the profession to lose no time in increasing the growing membership; but the talk about the decadence of the ASSOCIATION is, in the light of the facts, as silly as it is malicious.

Ten thousand new members would mean a great deal to the medical profession of this country, and

there is no visible reason why all do not march under the ASSOCIATION banner, except the constant tendency to split up into hundreds of small coteries. If there are errors in the form of the organization, such can be corrected at the will of the majority, and the practice of staying outside the fold and growling only pleases those who wish to see the organization belittled. The AMERICAN MEDICAL ASSOCIATION will not decay until the profession itself shall lose its reason and its patriotic instincts.

The logical force of the position held by those who uphold organization, is irresistible, and the tendency of the time, in all countries, is for better organization. A large body is more powerful to effect the accomplishment of the desires of the medical profession than a small one, and at this stage of our political history the only forces that are effective in moving legislatures, are those backed by numbers.

The scientific aspect of the ASSOCIATION has markedly improved since the creation of the Business committees of the Sections, and a glance at the papers published this year show a much higher average rank than heretofore. There were always "star" papers, but there were a number of mediocre papers. At the present time, the ASSOCIATION may take just pride in the high professional value of the papers sent to the JOURNAL from the Sections.

The JOURNAL itself has greatly benefited by the renewed vigor of the ASSOCIATION, and it can be made the equal of any medical journal published whenever the membership of the ASSOCIATION rises to equality in numbers with any other, and that membership will certainly come in time. The numbers are now increasing, but more slowly than befits this active, restless age. A little more vigorous effort to secure members by application will accomplish the desired result.

PERITONITIS IN THE MALE FROM GONORRHOEAL INFECTION.

The profession has already become quite familiar with the disastrous results of gonorrhœa in the female and its varied pathologic possibilities as affecting the pelvic peritoneum, and secondarily the general expanse of the peritoneum. The possibility of a similar infection of the peritoneum in the male has received very little attention, in spite of the fact that JOHN HUNTER many years ago called attention to peritonitis following in the train of epididymitis of gonorrhœal origin.¹ In HUNTER's opinion testicular inflammations of all sorts are generally accompanied by pain in the loins, and a sensation of weakness in the lumbar region and pelvis. The intestinal tract sympathizes ordinarily with most testicular diseases, said sympathy manifesting itself either by colic pains, or abnormal sensation located in the stomach and bowels. Nausea and vomiting are frequent symptoms.

¹ Works of Hunter, edition 1843, volume II, p. 219.

As a consequence of this gastro-intestinal disturbance the digestive function is deranged, and very painful, gaseous distension of the abdomen is likely to occur. There exists, according to HUNTER, a very complex series of sympathetic possibilities. The same is true of any irritation extending throughout the genito-urinary tract. Urethral disturbances are followed or attended by pain and irritation of the spermatic cord, the back, gastro-intestinal tract, and through these parts various disturbances of almost every other part of the body may occur. HUNTER further states his belief that this irritation may be communicated to the peritoneum through the canal of the vas deferens. The latter opinion he attempts to substantiate by a case in which pain and swelling of the right inguinal region immediately above Poupert's ligament occurred, with the phenomena of chills and fever following a gonorrhoea. On palpation, induration and pain were found to exist in this region, the pain extending over the entire abdomen. To HUNTER's mind these symptoms prove that the right vas deferens was affected by an inflammation which involved the abdominal and pelvic peritoneum. We, of modern days, with our knowledge of inflammation about the caput coli, find no difficulty in combating this view of HUNTER's as far as this particular case is concerned.

A very interesting article upon gonorrhoeal peritonitis in the male by ZEISL appears in the *Annales des Maladies des Organes Genito-Urinaires*, July 1893. It contains a complete bibliography of this subject up to date. Among the authors quoted in the article are SWEDIAUR, KERN, RICORD, FOURNIER, GODARD, VIDAL DE CASSIS, PETER, GUYON, BERKLEY HILL, TARNOWSKY, WENDELIN, GOSSELIN, ROUGON and HOROWITZ. Many of the cases quoted by ZEISL are decidedly defective, particularly in the direction of the possibility of confusion with "right iliac disease" i. e., appendicitis and its consequences. A case in point is one of Rorcoz's, which is as follows:*

An officer of artillery, at the age of 35 years, was taken in a dying condition to the Hôpital Fort de France (Martinique). The skin was cold and moist, face drawn and anxious, pulse small, frequent and almost threadlike. There was violent headache; the tongue very red, covered with sordes; extreme thirst was complained of. Patient was vomiting material colored with bile; abdomen was tender and very painful, principally in the right iliac fossa. Constipation had existed for several days. Urine had been scanty and high colored. Along the spermatic cord could be seen the relics of leech bites. Epididymitis of the right side, accompanied by acute hydrocele existed, with a history of gonorrhoea of twenty days duration, the secretion of which had suddenly ceased after the 14th of March, its cessation being followed

by testicular inflammation. The severe pain in the abdomen and other grave symptoms had already lasted for three days. Patient died the same day he was taken to the hospital.

Necropsy showed an abdomen distended with gas, scrotum bluish, with ecchymoses in the sub-peritoneal cellular tissue of the right side. The peritoneum, principally in the right iliac fossa, was covered with inflammatory exudate. About 300 grams of sero-purulent liquid were found in the right iliac fossa and the lower pelvis. The vessels of the serous envelope of the stomach, small and large intestine and principally the ascending colon, were highly injected. The liver was greatly distended with blood. The right epididymis was large, red and ecchymosed, and on section was found to contain four small purulent foci. The right spermatic cord was thickened, and was found to contain in its coverings a quantity of exudate. The prostate, seminal vesicles and ureter were not examined.

It is difficult to understand why the author should present this case in substantiation of the occurrence of gonorrhoeal peritonitis; a case was published by Rorcoz in 1876, the probability of the peritonitis following appendicitis and occurring as an accidental complication of epididymitis at once suggests itself. To the average American author, therefore, such a case would be absolutely worthless. NEUMANN, JULIEN, FINGER, MILTON and others mention peritonitis as a result of possible gonorrhoeal infection. MILTON, however, with his large experience, has never seen a case of the kind, neither apparently have JULIEN and NEUMANN.

HOROWITZ publishes two cases of peritonitis following epididymitis of the left side accompanied by prostatitis, inflammation of the seminal vesicles and considerable tumefaction of the left spermatic cord. Both of these cases recovered.[†]

ZEISL describes three cases of his own which he considers to have been peritonitis from gonorrhoeal infection.[‡] His first case may be taken as a type, and it is worthy of quotation.

F. X., 34 years of age, was attacked by urethritis about the 14th of November, 1879. He consulted ZEISL for the first time December 1, 1879. At that time there existed a temperature of 38.9 C.; pulse 106; tongue was dry; patient complained of vomiting from time to time matter of a bilious nature. The abdomen was slightly tympanitic and swollen, and especially sensitive to pressure in the right ileo-cæcal region. According to the story of the patient the symptoms developed on the night of November 30, 1879, after having already felt an acute pain in this location, and he had noted for a long time a swelling. There had been no constipation for several days, and no discharge of gas. The ensemble of symp-

* *Ann. Mal. gen.-ur.*, Vol. XI, p. 604.

† *Weiner Med. Woch.*, 1892.

‡ *Ann. des mal. gen.-ur.*, July, 1893.

toms pointed toward strangulated inguinal hernia. A careful examination of the patient found the serotum empty in the right side, with a painful tumor in the right inguinal canal. This was determined to be the testis. There was evidently in this case an inflammation of the right epididymis in a unilateral cryptorchid. Under frictions of mercurial ointment and the application of compresses of cold water, associated with hypodermic injections of morphine for the pain, the symptoms disappeared very speedily. On the 4th of December constipation ceased spontaneously, and after complete disappearance of the epididymitis, treatment of the urethritis was commenced.

Inasmuch as it has been shown that there is an intimate relation between the lymphatic supply of the genito-urinary tract and peritoneum, we are willing to accept the possibility of gonorrhoeal peritonitis in the male. We do not believe, however, that most of the cases cited by ZEISSL afford substantial evidence in favor of this pathological possibility. The local and constitutional disturbance incidental to strangulation of the inflamed spermatic cord or retained testis by the rigid and unyielding structures about it, are what we naturally expect to find in strangulation of a sensitive tissue, in whatever location it may be found. We have noted a similar group of symptoms to those outlined in ZEISSL's case in a number of instances of epididymitis in which there was a predominance of inflammation of the spermatic cord. Strangulation of tissues so intimately associated with the sympathetic ganglia, as are the spermatic cord and testes, particularly in the presence of acute inflammation and swelling, might be expected to be followed by more or less reflex irritation of the abdominal organs, general prostration, fever and disturbed heart action. Simple cases of epididymitis are very frequently attended by alarming manifestations of this character. Reflex inhibition of the intestinal muscle with resulting tympany are naturally to be expected in some of these cases. In some instances the onset of the difficulty is attended by profound manifestations of shock. Such cases as that of ZEISSL, followed by recovery, are seemingly very weak evidence in support of the possibility of gonorrhoeal peritonitis in the male. Fatal cases showing general peritonitis are equally valueless, unless it can be proven beyond peradventure of a doubt that there is no other cause for the peritonitis. Gonorrhoea and its sequelae are so frequent that it would be unfortunate, indeed, if the general practitioner were led to believe that gonorrhoeal peritonitis deserved great consideration in the matter of differential diagnosis. The possibility of its occurrence should be accepted, but should not weigh very heavily in the balance in cases in which symptoms exist that are strongly in-

dicative of appendicitis or general peritonitis from unknown but probably surgical remediable causes. It is hardly probable that such simple measures as were successful in the case quoted by ZEISSL could have very much effect after an acute peritonitis once begins. It should also be remembered that the peritoneum is not particularly susceptible to infection by the gonococcus per se; when it does occur in the course of gonorrhoea, even in the female, it should be attributed to a mixed infection, and not to the gonococcus.

CHOLERA.

In Russia, returns for the last week show a decided increase and its spread to localities heretofore uninfected. There was reported 4,329 new cases, and 1,692 deaths in twenty-two provinces. Turkey has quarantined vessels coming from nearly all the ports on the Black sea. The senate of Hamburg has prohibited the admission of clothes or dirty linen from Russia. Since August 15, there were eleven cases reported with eight deaths, in Germany. It is hinted that the river Spree may be infected. Suspicious cases were reported at Neuss, Halle, Duisburg, Sigmaringen, and a case of cholera was discovered in the Rhine boat *Flora*, at Rudesheim, opposite Bingen. There are now reported seventy districts of Hungary and seventy-two districts of Galicia infected with cholera, a decided increase over last week. The first case is also reported in Vienna. There seems to be a decrease at Naples, with a decided increase at Palermo, and denial that there is cholera in Rome. Roumania reports an increase. The disease seems to be increasing at Smyrna.

We have not yet learned the result of the distribution of the returning pilgrims that were quarantined at El Torr, save that eighteen deaths occurred on a French steamer that transported some of them to their homes. It is announced that the steamer *Carlos* arrived at Rio Janeiro on the 28th inst. from Grand Island, Canales, and that 103 persons on board died from cholera on the way over. The ship was refused permission to land or even put its crew and passengers in quarantine, and was escorted out of the harbor by the warship *Republica*, and ordered not to land at any Brazilian port. No official report has been received from France, but cases of cholera occurred at Montpellier, and a suspicious disease is reported at Nantes, which is undoubtedly cholera. One death from cholera is reported at Hull, England, a girl thirteen years of age.

In Holland and Belgium there is a slight increase, not alone in the cities heretofore reported, but also in the number of places infected. The lower part of the river Linga has been declared infected. We shall watch with much interest the efforts made by the health authorities of Germany, Belgium and Holland

to suppress and to prevent the spread of cholera. There are undoubtedly at this time more infected cholera points in Europe, than at any one time during the history of the various pandemics that have afflicted that country. These have generally lasted three years, but owing to the care taken, and the changes that have taken place in communication, it may be brought to an end this year. There is undoubtedly more cholera in Europe now, than is reported. So long as the present conditions obtain, the United States is not safe from invasion, and it is a question whether the time has not come when immigration should be suspended from all infected countries.

ARMY MEDICAL EXAMINING BOARD.

In our issue of July 29 we called attention to a circular of information for young medical men desirous of entering the medical department of the Army, and stated that a Board of Examiners would probably be convened in Washington, D. C. The Board has been directed to meet on September 11. Formerly these examining boards were convened in New York city; but as the professors of the new Army Medical School form a suitable personnel for them, it is likely that Washington will hereafter be their place of meeting. The officers detailed for duty on the Board now called into existence are: Colonel CHARLES ALDEN, president of the faculty; Lieut.-Colonel W. H. FORWOOD, professor of military surgery; Major CHARLES SMART, associate professor of military hygiene and director of the chemical laboratory; Captain W. REED, professor of clinical and sanitary microscopy, and Captain J. C. MERRILL, in charge of the property division of the Surgeon General's office. Although the Board meets in September it is not likely that its sessions for examination will be held until Monday, October 2. Some preliminary arrangements will have to be made, including the settlement of the details of a method of relieving candidates who would fail on account of physical or other easily discovered disqualifications from the loss of time, money and nervous energy involved in a needless journey to Washington. The post surgeon of the military station nearest to the home of the aspirant for position, will probably be called upon to examine into certain preliminary but essential points, and to submit his report thereon for the consideration of the Board. There are at present six vacancies, but the examiners will probably provide passed candidates for the prospective vacancies of the next twelve months.

LIABILITY FOR THE SUPPORT AND CARE OF THE INSANE.

States are wont to make some provisions for the care of their insane. They commonly levy special taxes for this purpose. Nebraska did this, but also

went farther and attempted to authorize a recovery, from the persons legally bound for the support of an insane person, of the sum paid by the county for the care and treatment of such insane person at the insane hospital of the State, when such care and treatment were furnished upon the finding of the proper commissioners of the county. This last enactment the Supreme Court of that State has declared unconstitutional and void, in a decision rendered in the case of *BALDWIN v. Douglas county*, on June 29, 1893, and just reported (55 *Northwestern Reporter*, 875). The court said that it had previously held that the relation of brother or sister to the afflicted did not justify this special exaction; and it had again adjudged the same freedom from liability as to the children of the insane. In this case, however, it was a husband that was sought to be charged, and it was insisted that he should be, because the husband is legally bound for the maintenance and care of his wife. But the court said that it knew of no principle of equity or justice that would imply a contract by the husband to answer for the treatment of his wife, furnished by the State in the interest of the general public; that the public thus benefited should defray all of the expenses incurred for its protection. Moreover, the husband had already paid his proportion for the maintenance of the insane hospital. This was by a direct tax upon his property. If he were required to pay for the treatment of his wife, such payment would be just as much a compulsory contribution to the maintenance of the insane hospital as was the other. It would be, in fact, another form of taxation for the same purpose. The right to levy taxes can only be justified as being necessary for the performance of its functions by the State. No tax can be legally levied for any purposes foreign to those functions, and even that far taxation is tolerated only from the necessities of the case. The collection of unnecessary revenues by the State is not taxation. It is robbery. The husband, here, having already paid his full proportion towards the maintenance of the insane hospital; more than that the authorities could not constitutionally exact.

HOSPITAL PHYSICIANS' ORGANIZATION.

The attending surgeons and physicians of Philadelphia have organized an association with the express object of extending courtesies to visiting physicians. The secretary of the association, Dr. H. H. WHARTON, keeps a roster of clinical lectures and demonstrations, and also a list of operations in prospect. In this way every visitor may learn, without delay, of operations in which he may be especially interested and the appointments of men whom he particularly desires to meet. On the other hand, the members of the association are promptly informed

of the presence of distinguished visitors in the city, so that proper attention may be given to them. Similar organizations should be in operation in all our medical centers.

TREATMENT OF CHOLERA AT THE NEW YORK QUARANTINE IN 1893

DR. BYRON, who was prominent in 1892 in the quarantine service of New York harbor, was in charge of the cases recently brought over by the *S. S. Karamania*. He has tried several plans of treatment, but his chief reliance is in the use of the irrigation method that seemed to work so well last year. The general facts with regard to the experiences in 1892 may be read in a leading article in the issue of this JOURNAL for May 20.

MEETING OF THE BOARD OF TRUSTEES.

The Board of Trustees of the AMERICAN MEDICAL ASSOCIATION will hold a session at the Arlington Hotel, Washington, D. C., on Monday, September 4, at 4 P. M. JOHN H. RAUCH, Secretary.

SPECIAL TRAIN OF THE JOURNAL.

The special train of the JOURNAL OF THE ASSOCIATION for the Pan-American Medical Congress will leave Chicago at 8 A. M. Sept. 3, from the new Illinois Central depot, 12th street and Park Row. Buy your tickets over the "Big 4" at the excursion rate. The railroad company promises that the accommodations of this train will be the best they can furnish.

NOTICE.—Gentlemen having business with the JOURNAL during the meeting of the Congress, will find the editor at the Arlington Hotel.

The President's Address will appear in full in the next issue of the JOURNAL.

DOMESTIC CORRESPONDENCE.

The Epidemic of Suicide.

To the Editor:—Epidemics of suicide are reported from London, Paris, Chicago and other large cities. On one day within the past week eight cases of attempted suicide with six fatal results occurred in Chicago.

Can we account for these melancholy facts, and furnish any promising remedy? It won't do to say that all these people are crazy. Some of them are far above the average in intelligence and thrift, have made deliberate preparations, and have acted and written with that calm contemplation and philosophical reasoning that discredit the theory of insanity.

Was Socrates insane? He courted death with utter indifference. Was Demosthenes insane when he preferred death to defeat? The past few days have furnished numerous instances in which insanity will not satisfactorily account for suicide.

The stringency in the money market will account for a certain proportion of suicidal deaths in the present epidemic, but not for such epidemics when times are not hard.

Then eliminating such cases as are attributable to trouble and insanity, how shall we account for epidemics of suicide, and what is the remedy?

When do these epidemics usually occur? In hot weather—July and August. But the heat of summer is not of itself necessarily depressing to a healthy nervous system. Otherwise why do not the people of the torrid zone exterminate themselves? But heat is favorable to the operation of a certain poison in the blood that produces, when in excess, contraction of the smaller arteries and capillary vessels all over the body, producing the cold surface and extremities, increased tension of pulse, slowing of the heart, headache, depression and irritability of temper. This same poison produces the pains of rheumatism, gout, angina pectoris, sick headache, paroxysms of nervous coryza, hay fever, and a long train of other symptoms.

The poison that has such a host of distressing symptoms charged against its action on the brain, the spinal cord or the solar plexus of nerves is uric acid.

The successful treatment for combating the effects of this poison is threefold: 1, palliative by immediate relief; 2, curative by elimination; 3, preventive by proper diet and active exercise.

1. When a person is suffering from mental depression, irritability of temper, headache, etc., due to the presence of uric acid in the blood, the first thing to do is to precipitate this acid by administering a dose or two of a mineral acid. This converts the blood into a poor solvent of uric acid. When the blood is the most alkaline, as it is in the early morning hours, it dissolves the uric acid that has been stored up in the more alkaline tissues and allows of its free circulation in the blood. It then produces its deleterious effects on the blood vessels and nervous centers. A few full doses of the mineral acids will free the blood of uric acid, relieve depression and irritability and produce a sense of satisfaction and well-being that is incompatible with the idea of self destruction.

2. After the immediate poisonous effects of uric acid have been overcome, remedies must be given to eliminate it from the system. This is best accomplished by salicylate of sodium in moderate doses, continued for a considerable time according to the individual indications. Five or ten grains taken every night for a few weeks or months may carry out of the system the uric acid that has been stored up for months or years as a result of improper diet and indigestion or faulty action of the kidneys.

3. Diet and systematic exercise will do the rest—prevent a return of the trouble. The proper diet for the uric acid diathesis consists of farinaceous foods, fruits, milk and fats. Meats, sweets, wine and beer produce lithemia and must be avoided. Fish and eggs may be allowed occasionally. Exercise sufficiently active to produce free perspiration should be taken systematically.

I believe that many cases of suffering and despondency with suicidal tendencies that come under our observation can be successfully treated on this plan.

S. S. BISHOP.

The Illinois State Board of Health.

The Illinois State Board of Health has issued the following circular:

SPRINGFIELD, AUG. 23, 1893.

Dear Doctor:—The Illinois State Board of Health is revising its Report on Medical Colleges and Medical Education, and is desirous of including in this edition all available information concerning every medical college in the United States, without regard to its standing, repute or school of practice.

Will you kindly furnish the Secretary, at your early con-

venience, a list of the medical colleges in your State, together with the names and addresses of officers, members of faculties, or others who may be written to for detailed information. Very truly yours, J. W. SCOTT, M.D.,
Secretary.

Cheese Poisoning Cases at Mansfield. Final Report.

MANSFIELD, OHIO, Aug. 14, 1893.

To the Editor—Dear Sir:—In compliance with my promise made some time ago to furnish you a report of the analysis of the cheese supposed to produce the numerous cases of so-called "cheese poisoning," in our city some weeks ago, I herewith submit you the same, together with the letter accompanying it from the Dairy and Food Commissioner, which is as follows:

Office of OHIO DAIRY AND FOOD COMMISSION, STATE HOUSE
DR. B. F. McNEAL, Commissioner, Columbus, O.
Geo. A. Root, Cincinnati, Assistants.
W. H. STEWART, Solon.

COLUMBUS, O., Aug. 12, 1893.

R. HARVEY REED, M.D., Mansfield, O.—My Dear Doctor:—Enclosed find report of analysis made by Prof. Kauffman of the cheese you sent to Dr. Probst. The other two chemists have not reported the results of their analysis yet, though one of them has intimated that tyrotoxin was present.

Will let you know the results of their work when I get their report. Yours truly, F. B. McNEAL.

OHIO DAIRY AND FOOD COMMISSION—DAILY REPORT OF
CHEMIST.

Serial No. 22. Received from Dr. F. B. McNeal. Date July 23d, 1893, marked ———.

N. — Date July 18, 1893.

Name of dealer, Mr. Herring. Sample of cheese.

Place of business, Mansfield, Ohio.

Name of producer, Mr. Maybee.—cheese said to contain poison.

Place of business, near Mansfield, Ohio.

Sample of cheese brought by Dr. McNeal.

Taken by Dr. R. Harvey Reed, health officer.

ANALYSIS.

Water, 30.116 per cent. Fat, 34.986 per cent. Casein and milk sugar 30.614 per cent. Ash, 4.284 per cent. Fat to total solids 50 per cent. pure butter fat.

No metallic poison found; etherial washings from aqueous extract gave positive reactions for tyrotoxin. Five minims of a solution of the etherial washings placed upon the tongue of a kitten immediately caused frothing at the mouth and in a few moments dryness of the throat, rapid breathing and retching; after about an hour violent purging. *Cheese contains tyrotoxin.* GEO. B. KAUFFMAN,
Chemist.

[Copy.] The fact that the investigation of Mr. Maybee's factory by the Food Commissioner, accompanied by an expert cheese manufacturer, has shown that tainted or spoiled milk had been used in the manufacture of the cheese, and in addition to this that two sick cows were found among the neighbors who furnished milk for the factory goes to show one of two things; either that tyrotoxin was the result of fermentation or the result of using milk from sick cows. While the milk of the latter may not have been good, yet at the same time we do not believe that that was the cause of the tyrotoxin, which we are inclined to think was the result of either spoiled milk in the first instance, or over fermentation in the preparation of the curd in the second instance. It is the custom of the cheese makers to allow it to stand until a certain degree of "acid," as they term it, is allowed to arise and when present makes cheese very light and spongy but which, in fact, is only the result of fermentation producing gases which penetrate the cheese during the process of pressing. This makes it light and porous, and at the same time is undoubtedly, when carried too far, the cause of fermentation followed by tyrotoxin, or possibly, in certain cases, other poisonous compounds of

a similar character, which we have already referred to in our former article, which Dr. Vaughn says he has found and isolated, the result of which those who have been studying this matter well know have been published by him. At the same time it is not always reliable to depend upon the chemist's analysis alone in these cases, unless you should find tyrotoxin or some of the other poisonous proteids and clearly demonstrate their existence by giving them to a kitten or some animal which is easily affected with such poisonous substances. When this can not be done satisfactorily a bacteriological examination should be had, and the nature and character of the germs determined in this way. It is well to make a bacteriological examination even where tyrotoxin is present, for as Dr. Vaughn well says "the exact nature of the poison present will depend upon the kind of germs producing it."

I am very glad that Prof. Kauffman has been able to obtain tyrotoxin in this case, as I have every reason to believe that it *does exist* in a large number of these cases of cheese poisoning, although in some instances the toxic effect may be due to other poisonous proteids.

The lesson we have learned from these cases seems to be clearly demonstrated, not only by the report of the expert who examined the factory, but by the chemical analysis that has followed,—that *over fermentation or decomposition of milk has been the prime cause of the whole trouble.* The sooner our State Boards of Health or, if necessary, the law makers of our various commonwealths, pass rules or enact laws which will prohibit cheese makers from allowing cheese to become over-fermented or to use spoiled milk for its manufacture the sooner we will find these cases of "cheese poisoning" diminishing. There is no more reason why a manufacturer of cheese should be allowed to let his cheese become fermented to such an extent as to produce poisonous compounds in order to make it light and salable, than there is for a baker to be allowed to mediate his bread or allow it to "raise" until it is sour in order to make it white, light and spongy.

Very respectfully submitted,

R. HARVEY REED.

Agnew's or Quimby's Operation?

DENVER COL., August 25, 1893.

To the Editor:—In the last issue of the JOURNAL I notice that in reporting the discussion upon Dr. Manley's paper on "Tarsal Amputations," Dr. Quimby is quoted as describing a modification of Pirogoff's amputation, and that other participants in the discussion are then quoted as calling this modified Pirogoff's procedure, "Quimby's operation." While it may be that the operation was original with Dr. Quimby, it was not necessarily originated by him, as it is described with brevity and clearness by Agnew in the second volume of his "Surgery," page 361, in the following words:

"Instead of sawing off the malleoli and the articular surface of the tibia, I allowed them to remain, and placed the calcaneum in the mortise between the two; the union was complete and was followed by a remarkably useful stump. In other instances I have done this and with satisfactory results."

Then follows a brief discussion of the new operation, and there is an illustration of a preparation obtained from a patient upon whom the operation had been done.

Respectfully,

WM. P. MESS.

A Treatment of Temulentia.

"*Dum loquimur tempus fugit.*" may be somewhat freely translated,—while we are discussing their methods the empirics (quacks?) are quietly raking in the duets. The fees exacted by the different cures range from \$105 up.

Any regular physician desirous of learning the writer's method for successfully combating alcohol addiction may address, (stamp enclosed.) C. M. FENN, A.M., M.D., San Diego, Cal.

BOOK NOTICES.

International Clinics: A Quarterly of Clinical Lectures on Medicine, Neurology, Pediatrics, Surgery, Genito-urinary Surgery, Gynecology, Ophthalmology, Laryngology, Otolaryngology and Dermatology, by Professors and Lecturers in the Leading Medical Colleges of the United States, Great Britain and Canada. Edited by JOHN M. KEATING, M.D., LL.D., Colorado Springs, Col.; JUDSON DALAND, M.D., Philadelphia; J. MITCHELL BRUCE, M.D., F.R.C.P., London, Eng. and DAVID W. FINLAY, M.D., F.R.C.P., Aberdeen, Scotland, Vol. I. Third Series, 1893. Pp. 360. Philadelphia: J. B. Lippincott Company.

There are fifty contributors to this volume, twelve of whom are British subjects and two French. They present a wide range of topics—seventy-five in number. The department of medicine occupies 121 pages, neurology forty-eight, pediatrics twenty, surgery sixty-four, genito-urinary surgery sixteen, gynecology and obstetrics forty-three, ophthalmology eleven, otology and laryngology twenty, and dermatology twelve.

In order not to trespass too much on the space in our plethoric JOURNAL, only a few notes can be culled on growing subjects that are exciting considerable discussion in medical circles.

A fair idea of the usefulness of the book as a representative of the progress in medicine, can be gained by referring to the lecture of Dr. W. H. Porter on Bright's disease. His work represents the best class of articles in this volume and he occupies ten pages with important teachings, the iconoclastic nature of which will shock the physiologists. His text is fresh and full of suggestions for rational methods of treatment and diet. On page 76 he says: "Bright's disease is not, as it used to be considered, equivalent to signing one's death warrant but, on the contrary, we can cure a large proportion of renal diseases. We must not look upon these diseases as local specific conditions belonging to the kidney alone, for all the lesions occurring in the kidney are secondary to physiological disturbances which have gone before, and our treatment should be directed not so much to the kidney as to these prior conditions."

While most books on physiology teach that glucose, albumin and proteid matters are diffused through the blood vessels, Porter claims that the albumin found in the urine is a by-product of incomplete oxidation thrown out by the epithelial cells, and that it is not filtered through the capillary blood vessels. He asserts that glucose has never been found as such in the blood, notwithstanding that it is commonly so stated in the works on physiology; but he maintains that it is produced by the renal cells, is not formed from the starches and sugar, but is a by-product resulting from incomplete oxidation. The glucose supposed to have been found in the blood by physiologists was the result of faulty tests.

The milk diet is used, together with ox bile in two or three grain doses of the purified inspissated bile three or four times a day, for its antipyretic action. He believes it is even more effective than the salicylates, which he uses to combat fermentation and heat production, and to favor heat radiation. He condemns the modern antipyretics as active poisons and powerful depressants to the cerebro-spinal centers. "One authority has been frank enough to state that he has killed patients with them."

About fifty or sixty cases of typhoid fever altogether have

been treated with ox bile without a single fatal result. Dr. Zeh has treated some of the worst typhoid cases, having very high temperature and with very severe hemorrhages from the bowels, with nothing else but inspissated bile and a little nitro-muriatic acid, with a well regulated diet and alcoholics when required, and not a single case has died.

Dr. W. O. Moore refers to a number of cases of exophthalmic goitre that were reported by Dr. A. M. Hamilton as having been absolutely cured by an aqueous solution of hydriotic acid in increasing doses. He classifies the disease as a purely nervous one, and does not believe there is yet any specific treatment. He presented a rare case in which the eyeball was literally dislocated through the commissure of the lids.

Dr. E. M. Crandall treats of rheumatism in children and maintains that salicylate of sodium does not fulfill all the requirements. While it relieves the subjective symptoms more promptly than any other remedy, it does not materially lessen the danger of endocardial inflammation. It does not increase the liability to cardiac involvement, although it is a cardiac depressant in large doses. He insists that although the alkaline treatment is slower, the cure is more permanent, and the danger of endocarditis less. He combines the two plans of treatment.

This book is like the previous editions and is a worthy addition to the progressive physician's library.

The Surgical Anatomy and Surgery of the Ear. By ALBERT H. TUTTLE, M.D., S.B., of Cambridge, Mass. With Twenty-eight Original Illustrations, reproduced from the writer's Drawings from Nature. Detroit: Geo. S. Davis. Paper. 1892.

Dr. Tuttle has furnished a little handbook of inestimable value to the aural specialist. It contains a brief account of what is most necessary for them to know in order to recognize the various affections of the ear and brain that require surgical operations, explanations of the various methods, together with directions for their performance.

The importance of this subject is mentioned on page 77 in the following words: "If we leave out the cases of tubercular meningitis and disease directly following and a result of trauma, comparatively few instances of suppurative inflammation of the brain or its meninges will be found associated with middle ear disease."

For the sake of brevity the author has sometimes sacrificed perspicuity. Some confusion results from the habit of using the terms drum and drum head synonymously. He advises the instillation of chloroform for killing insects in the ear, to be followed by syringing with warm water to wash the insects out. We have seen severe inflammation result from this use of chloroform by druggists. It is unnecessary, as the syringing alone does the work. If the ear is simply filled with warm water the live insect is drowned and floats to the surface.

In using the letters of reference to the illustrations it is often impossible to know to which figures they refer. The same remark might be made relative to the descriptions accompanying the excellent plates showing the various sections of the bone.

On page 45, in treating of operations for the removal of the drum head, the author misquotes Bishop, no doubt inadvertently. He says: "In 1885 Bishop reported fourteen cases of deafness operated upon by the removal of a piece of the membrana tympani without injuring the ossicles; although the patients all expressed themselves as hearing better, the writer could see no difference." Bishop said: "The operation improves hearing, and sometimes relieves distressing noises and other subjective symptoms when nothing else would."

However, the faults of this book are of minor importance. It gives the best résumé of the various aural surgical operations extant, and in such a concise yet comprehensive manner as to be of the highest value for ready reference. And it merits a more suitable cover than paper.

ASSOCIATION NEWS.

The American Medical Association in California.—Almost entirely through the efforts of our friend J. H. Parkinson, editor of the *Occidental Medical Times*, the National Medical Association voted to hold its next meeting in San Francisco. The society had about decided to go to Baltimore, when Dr. Parkinson in an energetic appeal carried the meeting in favor of San Francisco. Of course we are highly pleased with the result; the Association has come as near Los Angeles as we could reasonably expect this time.

The advantages of this choice are numerous. In the first place, hundreds of the leading physicians will visit California and many of them will come to the southern part of the State; their object will be to see the country, but incidentally they will learn that this is the best summer resort in America. It will be a good thing to be sized up by the doctors—we shall give them a hearty welcome; they in turn will treat us well and send us a new "one lung" brigade. Every one knows how the California Building at the World's Fair is crowded with eager, yet half doubting inquirers; now here is a chance to verify the claims made at the exhibition; let each community send a reliable doctor to spy out the land before the hosts of immigrants invade us. Another attraction for the Pacific Coast physician will be the Midwinter Fair which will probably continue until July.

In another and more favorable way this meeting will benefit the profession of California; new interest and added enthusiasm will be gained in professional work; increased knowledge and added proficiency of all participants will be great inducements for a large attendance of the physicians of our State. It might be added here that to be a member of the National, one must belong to the State Society, and to belong to the State, one must be a member of the County Association and to hold a membership in the County Society it is necessary to keep the dues paid up, which amounts in this county to two dollars a year. The moral is obvious.—*Southern California Practitioner*, August, 1893.

SOCIETY NEWS.

Pan-American Medical Congress—HOTEL RATES AND CAPACITIES:

Hotel Normandie—Two in room \$4.00. One in room \$5.00 per day. American plan. Accommodations for 100.

The Arlington—\$4.00 and \$5.00 per day. Accommodations for 500.

Cochran Hotel—\$4.00 and \$5.00 per day. Accommodations for 50 to 75.

Wormley Hotel—\$4.00 per day. Accommodations for 100. Randall Hotel—\$2.50 and \$3.00 per day. Accommodations for 75 to 100.

Willards and Riggs—\$3.50 to \$4.50 per day. Accommodations for 100 to 500.

Arno—\$1.50 to \$2.50 for room, European, and \$3.00 to \$4.00 per day, American.

Shoreham—\$2.00 to \$3.00 for room, European. \$1.00 to \$5.00 American. Accommodations for 200.

National Hotel—\$2.50 to \$4.00 per day.

Elbirt House—\$3.00, \$3.50 and \$4.00. No extra charge for alcove parlors.

The Dominion Medical Association meets in London, Ontario September 20 and 21.

NECROLOGY.

Dr. Norris M. Carter of Brooklyn, died at his home on the 11th of August, from an affection of the heart, that had been of some months' duration. He was 52 years old, a native of the northern part of Ireland. He came to New York in early youth and received his medical education at the Albany Medical College, graduating in the class of 1859. During the war, he served as contract-surgeon. He made his home in Brooklyn about fifteen years ago, and rapidly acquired fame and position in one of the best sections of that city. He was a manly man, with genial aspect and commanding bearing. His judgment was sound, though not rapid, and his convictions firm and even frankly expressed. His physique and mental endowments, both, seemed to conspire to give to Dr. Carter the promise of a long and satisfactory career in his profession, but fate had appointed for him to fall while yet in the prime of his powers.

Death of an Eminent Medical Missionary.—The *London Christian* contains the following tribute to an American missionary to China, the Rev. Edward P. Thwing, M.D., formerly of Brooklyn, New York. He was probably the pioneer worker in the far east, who had set for himself the task of showing how the insane should be treated. "Dr. and Rev. Edward Payson Thwing died at Canton, China, on May 9. He was born at Ware, Mass., on August 25, 1830, and graduated from Harvard University in 1855, and from Andover Theological Seminary in 1858. He preached in Portland, Me., Quincy, Mass., and in the Church of the Covenant, Brooklyn. A few years ago he took a medical degree at the Long Island College Hospital. For several years he preached during the summers in London, and lectured frequently in New York, Brooklyn, and other places. He was a frequent contributor to the magazines. He visited China two years ago, and became impressed with the need of hospitals and asylums there, and went to that country again last year. At the time of his death he was in charge of the building of an asylum. One of his sons is a medical missionary in Alaska, another is a medical missionary in China, and a third lives in Brooklyn. There are three daughters in the family."

Dr. Courtney J. Clark died at Jacksonville, Ala., August 18. Dr. Clark was born in Laurens district, South Carolina, October 27, 1816, his parents being native residents of that State. He received his early education in Georgia and commenced the study of medicine when only 18 years old. He graduated from the College of Medicine, of Louisville, Ky., in 1843, and in 1844 from Jefferson Medical School at Philadelphia.

In 1847 he settled in Jacksonville, Ala. When the Mexican war broke out Dr. Clark was appointed by President Polk, surgeon in the United States army and served with Butler's Palmetto South Carolina regiment, being with that gallant command in all its battles up to the capture of the City of Mexico.

During the late war Dr. Clark was surgeon in the Confederate army. Starting out as a regimental surgeon, he was soon transferred to the charge of the Alabama hospital in Richmond, afterward to the hospital in Montgomery and then to Columbus, Ga., at which point he was stationed when he gave his parole to General Wilson at the end of the war.

Dr. Clark was a resident of Selma and practiced his profession there since 1865 and no citizen has ever been held in higher or more affectionate esteem. He was an ardent advocate of the educational interests of the city, holding the responsible position of president of the city school board of

Selma for a number of years, always zealous in the performance of his duties, and it is no exaggeration to say that no citizen of Selma has contributed more to the upbuilding of the public school system than this loved and honored physician. He was for several years president of the Selma Medical Society, a prominent member of the State association, a forcible writer in several of the leading medical magazines and he stood in the front rank of his profession as one of the leading practitioners and surgeons in the South.

In 1853 Dr. Clark was married at Jacksonville, Ala., to Miss Nancy W., daughter of Thomas J. Davis. Five children survive this union: Percy Clark, of Washington, D. C.; Mrs. J. C. Ware of Montgomery; Mrs. A. J. Harris, Mrs. T. H. Lewin and Misses Julia and Jessie Clark, of this city.

Dr. WILLIAM S. HURD, a well known physician of Paterson, N. J., died Aug. 18, after a long illness. His system never fully recovered from blood poisoning, the result of an accidental cut received while performing an autopsy some years ago. He was born at Fishkill Landing, N. Y., in 1847, went to Paterson with his parents when a boy, and at the age of 17 enlisted in the 55th regiment, serving during the last year of the war, and becoming a corporal. He was graduated from the College of Physicians and Surgeons in New York in 1877, at the head of his class. In 1878 he was elected assistant city physician of Paterson, and served five terms by yearly re-election. He also served a three year term as coroner of Passaic county. In politics he was a republican. During the smallpox epidemic of 1882 he did devoted service for the city, breaking down his health and losing most of his private practice, which it took several years to reestablish. He was a skillful caricaturist, contributing occasional sketches to illustrated periodicals, and was an amateur actor of Shakespearian tastes. He was a member of the Knights of Pythias and of the Passaic County District Medical Society. Dr. Hurd was a member of the United States Medical Examining Board for the 6th Congressional District of New Jersey. A wife and daughter survive him.

Dr. JAMES O'RORKE died at his home in West Forty-sixth street, on Sunday, July 30, 1893. The deceased was a graduate of the Jefferson Medical College of Philadelphia, of the class of 1847, a consulting physician to St. Vincent's hospital, a practitioner held in high esteem by his professional brethren and by the community.

Dr. GEORGE W. BENSON of Baltimore, Md., died August 22. Dr. Benson served two terms as health commissioner. During Dr. Benson's term two smallpox epidemics prevailed—in 1872 and again in 1892. Much credit was given the health officer for the excellent judgment displayed and the speedy stamping out of the dreaded scourge.

He was born April 8, 1831, in Princess Anne, Somerset county, Md. When 17 years of age he accepted a position in a drug store in this city. Three years later he was graduated at the Maryland University. He began the practice of medicine, having for many years an office on Hanover street, near Hill. In 1856 he was coroner of the Southern district, serving two terms. He was regarded in the southern section of Baltimore as one of the most eminent physicians of his time. Dr. Benson married Miss Susie E. Dexter, of Chelsea, Mass., in 1852, who died, leaving one son, Morton, in 1874. Fifteen years ago he married Mrs. Susan Waite, who survives him.

Dr. Benson has for the past year been a sufferer from Bright's disease of the kidneys and heart failure. Being a man of iron nerve, he bore up under the affliction and continued his large practice until about one month ago, when he was compelled to remain indoors. A few days later he

was unable to leave his room, and remained in bed until his death occurred.

Dr. GEORGE F. THORNTON died Aug. 15, 1893, at San Francisco. Death resulted from paralysis. Dr. Thornton was a native of Green county, Alabama. He received his education at the Alabama State University and the New Orleans Medical College. During the late war he served as surgeon in the Confederate army, and in 1869 came to California. Dr. Thornton was in 1871 one of the leading spirits in the Newark Land and Transportation Company, and was for a number of years manager of large land interests in Kern county. He leaves a widow, three sons and a daughter.

Dr. C. C. RADMORE, aged 65, died at Lincoln, Neb., Aug. 19. Dr. Radmore was a native of Pennsylvania and was a soldier in the Mexican war as well as the late civil war. He practiced in Winona, Ill. During the war he was connected with the 4th and 107th Illinois regiments and was successively brigade and corps surgeon. He came to Lincoln in 1868, where he has since resided.

Dr. ISAAC PARKER of Morgan county, died at Chester Hill, O., aged 78 years. He resided at Chester Hill for 50 years, was the pioneer physician of that county, and was well and favorably known all over the county. His death was the result of age.

Dr. A. S. LUSE, a California pioneer and an old resident of Los Gatos, died at his home in that city, Aug. 14, 1893. The deceased was 74 years of age, born in Mount Pleasant, Westmoreland county, Pa.

Dr. HARRISON S. GARDNER of Cedar Springs, died in Grand Rapids, Mich., August 22d. He was 53 years old and a well known citizen of Cedar Springs, and past master of Cedar Springs Masonic lodge.

Dr. CHAS. L. SEEMAN of New Orleans, died August 15th. He was a graduate of Tulane University, and coroner of New Orleans for the past year.

Dr. J. W. REDDEN died at Topeka, Kan., Aug. 5. Dr. Redden was a native of Delaware, educated at Dickinson College and a graduate of Jefferson Medical College. He was formerly Secretary of the Kansas State Board of Health.

Dr. J. W. BRANHAM, Asst. Surgeon U. S. Marine Hospital Service, died of yellow fever, at Brunswick, Ga., August 20, 1893. Dr. Branham had only recently been appointed.

Dr. S. J. F. MILLER of Augusta, Me., formerly superintendent of the Dayton (Ohio) Insane Asylum and surgeon of the Soldiers' Home at Milwaukee, died Aug. 7.

Dr. H. KNAPP of Lathrop, California, died August 14, 1893. He was 80 years of age.

Dr. LEE M. BENTLEY died near Coffeyville, Ark., August 19th, 1893.

Dr. HORACE B. Sisson, a resident of Ottumwa, Iowa, since 1854, died at his home Wednesday at the age of 72 years.

Dr. GEORGE H. WALLING of Louisville, father of Dr. Willoughby Walling, died at Louisville, Aug. 21.

Dr. J. B. NEWMAN of Great Falls, Montana, August 13, 1893.

Dr. HARRY SEDGWICK of Martin's Ferry, Ohio, August 19.

Dr. THOS. E. COOPER of Allentown, Pa., August 18.

Dr. KUNZ of Monticello, Iowa, August 19.

MISCELLANY.

Dr. Samuel C. Schmucker.—Dr. Samuel C. Schmucker, recently elected professor of chemistry in the Colorado Agricultural College at Fort Collins, comes from the University of Pennsylvania. He received his A. B. from Muhlenburg college in 1883, and his S. B. in 1884. During 1884-85 he was professor in Carthage College, Illinois, and subsequently was professor of chemistry in the boys' high school, Reading, Pennsylvania. Later he held the chair of natural sciences in the Indiana, Pennsylvania, normal school. Dr. Schmucker has pursued post-graduate studies in the University of Pennsylvania for three years, his major subject being chemistry. The subject of his thesis, which is now in press, is "The Electrolytic Separation of the Metals of the Second Group."

Prizes for Life Saving Needed.—An inquest, recently held near London in reference to the death of a lad found drowned in a canal, revealed the fact that the boy was allowed to drown alongside a canal boat, although there were a number of boatmen looking on. There is a reward offered for the recovery of a body, but none for saving life. The reward amounts to five shillings and was sufficient to deter those men from putting forth a hand to save the dying lad. It was testified that it had been observed several times before that canalmen have stood idly by while persons were struggling for life in the water. The coroner explained that there had formerly been a prize offered for the rescue of drowning persons, and that men would push one another into the canal and afterward claim the rescue money. This was more than the vestrymen would stand. The consequence has been that not a few innocent lives have been lost through accidental drowning that might readily have been saved.

Army Hospital Corps—A New Company of Instruction.—It is understood that the Surgeon General of the Army will organize a company of instruction at Washington Barracks, D. C. The two companies at present in existence are stationed at Fort Riley, Oklahoma Territory and Fort D. A. Russell, Wyoming. These stations were originally selected on account of their central position, so as to lessen the expense of transporting trained men from the companies to their posts. The surgeon general, however, regards the location of one of these companies as a mistake. Many men are recruited from the cities of the east who, under present conditions, have to be sent to Fort Russell for their training and afterwards back to the east for duty at some seaboard station. This may be avoided by having one of the companies of instruction in the east, and General Sternberg is understood to prefer Washington Barracks as the company will there be available for service in connection with the Army Medical School. Young medical officers on duty at the latter will have opportunity of becoming acquainted with the methods of drawing food and clothing for the men, keeping their accounts and other matters of company administration. Instead of transferring the company from Fort D. A. Russell to Washington a new company will be organized at the latter place, and the organization of the old company will be permitted to lapse when its members have been drafted off to their permanent posts. The company at Fort Riley will be retained as being in a suitable location for the supply of western posts with trained men. The organization of these companies is said to have had gratifying results, the qualifications of the men who have had the benefit of the special course of training and study being considered much superior to those of men trained at the post hospitals.

Higher Medical Education.—The establishment of the Johns Hopkins Medical School, and the College of Physicians and Surgeons of Richmond marks a new era in medical education south of Mason and Dixon's line. For a number of years the Johns Hopkins has been laying the foundation for the school, and from present indications it will be thoroughly equipped. Four annual courses of lectures will be required, and a high preliminary entrance examination. The College of Physicians and Surgeons will comply with the requirements of the American Medical College Association. Several of the older schools will also commence the requirement of a fourth year course, and the indications are that the day is not far distant when the facilities for acquiring a medical education in this country will be equal if not superior to those of the older institutions in Europe.

Small Caliber Projectiles.—During the past year Dr. LaGarde of the army, has conducted a series of experiments to determine the character of the wounds caused by small caliber projectiles on the human body. The experiments were performed at Frankford Arsenal, Pa., with rifles and bullets prepared by the Ordnance Department specially for the occasion. The calibers used for comparison were .45" and .30". The range of explosive effects was greater with the latter, extending as far as 350 yards, and at such ranges shock was severe, apertures of entrance small, inverted and often blackened, and those of exit larger and everted, the soft parts extensively ruptured and the bones shattered. Beyond this range there was much less disorganization in the track of the smaller than of the larger bullets; but at from 1,500 to 2,000 yards, when the velocity became lessened, the effects again took on the character of those at the shorter ranges. Dr. LaGarde's experiments embraced also a determination of the heat imparted to projectiles by firing and impact; the influence of firing on germs present on the bullet, and the comparative penetration and destructive effects of various hard metal cased projectiles. The last mentioned series of experiments formed the subject of a paper read by him at the meeting of the Association of Military Surgeons of the National Guard of the United States reported in our issue of August 19th. It is expected that a full report of the experiments conducted at the Frankford Arsenal will be published in the forthcoming report of the surgeon general of the army.

Scurvy at a County Lunatic Asylum.—Commissioner Reeve of the New York State Board of Charities, is reported in the daily press as charging grave mismanagement at the St. Johnland asylum, which is the country branch of the Kings county asylum. He alleges that scurvy has appeared more than once among the insane paupers, as the result of an inadequate supply of fresh vegetables. Of the 900 acres belonging to the St. Johnland plant, not less than 200 are eminently suitable for the cultivation of antiscorbutic vegetables; there is an abundance of available labor among the inmates, whose health would be the better if they were intelligently employed in the fields; there is a farmer superintendent, who is without implements. Yet for days together the only vegetable food of an antiscorbutic character has been dried apples. "This is but one of a multitude," says the official, "of acts of a similar tendency that have come under our observation." And he added: "And when the epitaph of St. Johnland is written, let the words 'Flagrant and criminal waste of public money' be inserted at all hazards." The question will most certainly arise in some inquiring minds whether or not the State Commissioners of Charities have done their full duty after coming to the knowledge that scurvy has been superadded to insanity, in the cases of these unfortunate St. Johnland inmates and have not made an official declaration of that knowledge.

Typhus Fever at a Summer Resort.—At the Manhattan Beach Hotel, Coney Island, there has been discovered a case of typhus fever, in the person of one of the hotel employes. The patient was a yard man whose duties brought him in contact with the food supplies of the house, at the time of

their reception from the freight cars. This was the only case known in the vicinity of New York for several weeks, and the health authorities had been felicitating themselves over the complete stamping out of the recent plague. It is not certainly shown that the patient contracted the disease in New York city; in fact, the officials having charge of its investigation incline to the theory the man was exposed to contagion at some place in Pennsylvania. But the name of the place is unknown or unreported. The patient was removed to Bellevue Hospital, and thence to the North Brother Island fever hospital. The case was at first considered one of alcoholism. The roommates and fellow yardmen were ordered to be isolated. The outcome of this unusual occurrence will be interesting.

Minnesota State University.—The board of regents of the State University held a session August 18, at the capitol, and reached a final decision regarding the new library and assembly hall. The revised plans prepared by Architects Bullington & Eldridge of Minneapolis, were submitted and were accepted with some minor changes. The building is not to cost more than \$155,000, including architects' fees and salaries. The selection of the stone for the building and a superintendent have been left to committees.

Dr. H. M. Reynolds has been appointed veterinarian of the schools at a salary of \$500 a year.

The following resolutions, which were adopted, were presented by Mr. Northrup:

Resolved, That the four colleges of the medical department be made independent, their interests being managed by their own faculty, subject to the board of regents; that the office of dean of the department of medicine be abolished, and Perry W. Millard be appointed dean of the college of medicine and surgery; that the executive committee of the medical department be abolished; that the professors of chemistry, anatomy, physiology, histology and embryology in the college of medicine and surgery be made also professors in the department of medicine, and as such instruct all students in the four colleges; that an additional room be furnished in the medical building for the homeopathic college when needed, and that the medical building be so used as to meet the wants of all the colleges impartially; that the matter of rooms and the necessity for four rooms for deans, the proper salary to be paid to Dean Millard, and the desirability of having a registrar to attend to the records of the four colleges respectively, students and their standing, to receive all bills, see that they are approved by the proper dean and duly presented to the executive committee, and attend to any other matters of common interest to the college outside of the work of instruction, be referred to the committee on the medical department to consider and report at their earliest convenience.

The following was handed in by the homeopathic faculty, but no action was taken by the regents:

First—That the department of homeopathic medicine and surgery shall have a full faculty appointed in all branches excepting those of chemistry and histology.

Second—That if this be impracticable, the primary branches—anatomy, physiology, chemistry, pathology, etc., shall constitute a department of the college separate and distinct from the various colleges in the department of medicine.

Third—That the college of homeopathic medicine and surgery shall be independent and its dean responsible directly to the president and board of regents.

Fourth—That the homeopathic department be given more room in the present building.

Indiana Northern Hospital.—A warrant was drawn Aug. 17 by the State Auditor of Indiana in favor of the Northern Hospital for the Insane for \$2,981.23, on account of the extension of the building and other improvements. The principal part of the extension includes the new dining room. The same hospital also received \$6,991.75 for current expenses. The Southern hospital was allowed \$5,596.21.

Agency Physician.—Dr. W. Wyman has been appointed physician to the Indian Agency at Leech Lake, Kansas.

Railroad Hospital.—Logansport.—A hospital is to be erected at Clifton Forge by the Chesapeake & Ohio, where all disabled employes of that road will be sent. The company has appropriated \$25,000 for its erection.

The State of Rhode Island and Providence Plantations is building a hospital for the old soldiers at Bristol, in connection with the Soldiers' Home, to cost \$15,000.

The Journal will be found on sale at W. T. Keener's, 961 Washington Street, Chicago, and at W. H. Lowdermilk & Co's, F Street, Washington, D. C.

College Appointment.—Dr. C. D. Aaron has been elected professor of anatomy by the faculty of the Detroit College of Medicine.

New Hospital.—A new hospital is to be built at Grand Rapids, Mich., under the auspices of the Sisters of Mercy.

Cholera.—A case of cholera was reported at Jersey City Hospital, August 30.

THE PUBLIC SERVICES.

Notice.

An Army Medical Board will be in session at Washington, City, D. C., during October, 1893, for the examination of candidates for appointment to the Medical Corps of the United States Army to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before September 15, 1893, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 22 and 28 years of age, and a graduate from a Regular Medical College, as evidence of which, his diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon General U. S. Army, Washington, D. C.

GEO. M. STERNBERG, Surgeon General U. S. Army.

Museum of Hygiene, Medical Department, U. S. Navy.

This institution, which has its home at 1507 New York avenue, Washington, D. C., was founded and officially recognized by Congress in 1883. Since then it has grown under the fostering care of Surgeon General John M. Browne, Medical Director Philip S. Wales, and Surgeons White, Kidder, Owens, Ames and others. Its catalogue, recently issued to indicate the extent and direction of its growth, is an octavo pamphlet of 124 pages, which contains a list of about two thousand specimens illustrating conditions of local hygiene pertaining to soil, air, the construction of dwellings and their aggregation into towns and cities, and of course the construction of ships with their heating, lighting, ventilation, air space and other accommodations or lack of accommodations does not fail to take a prominent place in the collection. Food supplies, clothing, safety appliances in traveling by land or water, protection against fire, etc., disinfection and the care of wounded men also find satisfactory provision for their illustration. The catalogue gives carefully prepared descriptions of so many of the specimens that a perusal of its pages would to many minds be almost equivalent to a personal inspection of the institution. If the existence of the Museum were more generally known there is no doubt that it would become the depository of many specimens at present isolated in the cabinets of medical men and therefore almost valueless for educational purposes. We commend the Museum of Hygiene and give increased publicity to the desire of its director, Medical Director Wales, to extend the sphere of its usefulness.

Retirement of Dr. Bloodgood, U. S. N.

Medical Director Delavan Bloodgood, whose retirement took place August 26, by reason of his having attained the age of 62 years, will reside in Brooklyn permanently hereafter. His long and faithful service has been conspicuous, and this officer is known among his colleagues in the American Medical Association as one of the most genial and accomplished officers among the brilliant corps from time to time delegated to attend the annual meetings. Doctor Bloodgood, although retired from the Navy, has not been retired from the Association, where his many friends will welcome him, they trust, for very many years to come.

Marine Hospital Service.

The following circular has been issued by the acting secretary of the treasury:

United States Quarantine Rules to be Observed in Places Infected with Yellow Fever.

TREASURY DEPARTMENT, OFFICE OF THE SECRETARY.

WASHINGTON, D. C., August 12, 1893.

To medical officers of the Marine Hospital Service, quarantine officers in the United States, and other concerned.

Pursuant to the act of February 15, 1893, entitled "An act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service," the following regulations have been made thereunder and hereby promulgated according to the terms of the act:

1. All persons affected with yellow fever, or who are believed to have been exposed to the infection, will be so isolated under observation and free from infection and all their effects properly disinfected. Communication with infected persons will not be allowed except for the necessary conveyance of supplies, etc., which must be under the supervision of a fully qualified medical sanitary inspector.

2. The localities contiguous to those infected and infected localities, so far as it may be safely done, should be kept as rapidly and as completely as possible, persons from non infected localities, and who have not been exposed, leaving without detention; those who have been exposed, or who come from infected localities, being required to undergo a period of detention, from date of last exposure, in camps of isolation. The clothing or anything capable of conveying infection shall not be allowed to leave the infected locality without disinfection.

3. Camps of isolation shall be inspected twice daily or oftener, and the inspectors should be conversant with the proper health authorities, such daily inspection shall be provided for each isolation camp.

4. When practicable, camps of detention should be provided for those who require it.

5. Buildings in which cases of yellow fever have occurred, and localities believed to be infected, must be disinfected as thoroughly as possible.

6. As soon as the disease shall have been declared epidemic, the railway trains carrying persons who may be allowed to depart from the railway place infected with yellow fever shall be under medical supervision. A medical sanitary inspector should accompany each train when practicable, and enforce prompt isolation of any person who may be attacked with the disease, and report the same immediately to the proper health authorities. Where no facilities for the proper health authorities, if necessary, the railroad companies should be required to attach an extra car for hospital purposes to each train carrying persons from an infected place, which may be side tracked at some safe and convenient locality on the road.

CHARLES S. HAYLEN, Acting Secretary.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from August 19, 1893, to August 25, 1893.

By direction of the Secretary of War, a board of medical officers, to consist of Col. CHARLES H. ALDEN, Asst. Surgeon General; Lieut. Col. W. H. FORKUM, deputy Surgeon General; Major CHARLES S. WART, Surgeon; Capt. WALTER REED, Asst. Surgeon, and Capt. JAMES C. MERRILL, Asst. Surgeon, is constituted to meet at the Army Medical Museum Building in this city, on the 15th day of September, 1893, for the examination and recommendation for promotion to the Medical Corps of the Army. Par. 1, S. O. 134, A. G. O., Hdqrs. of the Army, Washington, August 24, 1893.

By direction of the Secretary of War, the following named medical officers are detailed to represent the Medical Department of the Army at the Pan American Medical Congress to be held in Washington, D. C., September 25, 1893: Col. R. J. D. LEWIS, Asst. Surgeon General; Lieut. Col. DALLAS RAGLE, deputy Surgeon General; Major JAMES H. H. WARD, Surgeon; and Major CHARLES S. WART, Surgeon. A board of officers to consist of Col. CHARLES H. ALDEN, Asst. Surgeon General; Lieut. Col. W. H. FORKUM, deputy Surgeon General; Major JOSEPH K. CONSON, Surgeon; is by direction of the Secretary of War, appointed to meet at the Army Medical Museum Building, Washington, D. C., Monday, September 1, 1893, for the examination of such officers as may be detailed before it, to determine their fitness for promotion.

Col. CHARLES H. ALDEN, Asst. Surgeon General, on being relieved from duty as medical director Dept. of Dakota, will proceed to this city and assist to the Surgeon General U. S. A. for duty in his office, and as president of the Army Medical school, Washington, D. C.

Capt. J. L. POE, Asst. Surgeon U. S. A., is hereby granted leave of absence for one month, with permission to apply for an extension of ten days.

Lieut. Col. W. H. FORKUM, deputy Surgeon General, is relieved from duty at the Medical Museum Building, New York, and assigned to duty as medical director Dept. of Dakota, to be relieved by Major CHARLES S. WART, Surgeon, deputy Surgeon General U. S. A., Lieut. Col. C. B. BARNES, deputy Surgeon General, on being relieved from duty as medical director Dept. of the Columbia, will report his duties as medical director Dept. of Dakota, to Lieut. Col. R. J. D. LEWIS, Asst. Surgeon General.

Capt. PAUL SHILLICK, Asst. Surgeon (on the field), is granted leave of absence for one month, to take effect about September 1, 1893, with permission to apply for an extension of fifteen days. The commanding officer F. S. A. in the field near Prattland, N. M., is authorized to employ a citizen physician in cases of necessity during absence of Capt. PAUL SHILLICK, Asst. Surgeon.

Capt. W. M. F. CALVERT, Asst. Surgeon, is granted leave of absence for one month, to take effect about the 15th of Asst. Surgeon GILMAN S. PROCTOR.

Major DEWEES M. BROWN, Surgeon, is relieved from duty at Ft. Meade, S. D., and assigned to duty at Ft. Wayne, Mich.

Capt. M. A. WARD, Asst. Surgeon U. S. A., is granted leave of absence for one month, to commence about September 1, 1893.

Capt. R. J. CONSON, Asst. Surgeon U. S. A., is granted leave of absence for one month.

By direction of the Secretary of War, the following named officers will report in person to Col. C. H. ALDEN, Asst. Surgeon General, president of the examining board appointed to meet at the Army Medical Museum Building, September 1, 1893, for examination for promotion: Col. R. J. D. LEWIS, Asst. Surgeon; Lieut. Col. J. L. POE, Asst. Surgeon; Capt. JAMES C. MERRILL, Asst. Surgeon; Capt. WALTER REED, Asst. Surgeon; Capt. JAMES C. MERRILL, Asst. Surgeon.

Navy Changes. Official list of changes in the Medical Corps of the U. S. Navy, for the week ending August 26, 1893.

M. D. Director D. BROADBENT, placed on retired list August 25, 1893, and succeeded by W. W. WATSON, from "Monterey," and to the "Philadelphia."

Medical Director A. A. HOEHLING, president of board to examine applicants for Naval Academy.

P. A. Surgeon G. T. SMITH, from "Baltimore," and to "Wabash," P. A. Surgeon R. M. KENNEY, from "Wabash," and to the "Baltimore," Asst. Surgeon L. H. STONE, from hospital, New York, and to the "Minnesota."

Asst. Surgeon J. E. PAGE, from the "Minnesota," and sick leave for three months.

Marine Hospital Changes. Official list of changes of stations and duties of medical officers of the U. S. Marine Hospital Service, for the eight weeks ended August 5, 1893.

Surgeon C. S. D. FESSENDEN, to proceed to Mobile, Ala., for duty, June 16, 1893. To proceed to New Orleans, La., as inspector, August 1, 1893.

Surgeon F. A. DE MEYER, granted leave of absence for seven days, June 21, 1893.

Surgeon JOHN VANSANT, to proceed to Wilmington, N. C., for duty, June 16, 1893.

Surgeon H. W. ALSTON, to inspect Delaware Breakwater Quarantine Station, July 22, 1893.

Surgeon J. M. GASSAWAY, to proceed to Detroit, Mich., and Chicago, Ill., as inspector, July 12, 1893.

Surgeon F. A. DE MEYER, detailed for duty in office of the U. S. Consul, London, Eng., July 2, 1893.

Surgeon H. R. CARTER, to proceed to Brunswick, Ga., for temporary duty, June 28, 1893.

P. A. Surgeon T. T. PECKHAM, granted leave of absence for six days, June 22, 1893.

P. A. Surgeon S. D. BROOKS, granted leave of absence for three days, June 22, 1893.

P. A. Surgeon W. C. CARRINGTON, detailed for duty in office of U. S. Consul, Bremen, Germany, June 15, 1893.

P. A. Surgeon J. J. KINROSS, to resign station, Washington, D. C., July 10, 1893. To inspect Camp Low, N. J., July 29, 1893.

P. A. Surgeon W. T. GOODWIN, granted leave of absence for three days, June 12, 1893. To proceed to Louisville, Ky., for duty, July 12, 1893.

P. A. Surgeon G. T. VAUGHAN, to proceed to Chicago, Ill., for temporary duty, July 16, 1893.

P. A. Surgeon H. C. O'BRIEN, to proceed to Delaware Breakwater Quarantine, July 20, 1893.

P. A. Surgeon J. C. PERRY, to proceed to Portland, Me., for temporary duty, July 8, 1893.

Asst. Surgeon W. C. STEPHENSON, detailed for duty in office of U. S. Consul, Glasgow, Scotland, July 7, 1893.

Asst. Surgeon C. H. GARDNER, granted leave of absence for fourteen days, July 19, 1893.

Asst. Surgeon E. G. GORRAVEY, to proceed to Vineyard Haven, Mass., for temporary duty, July 8, 1893.

Asst. Surgeon J. H. OAKLEY, to proceed to Wilmington, N. C., for temporary duty, June 24, 1893.

Asst. Surgeon NATHAN NORMAN, granted leave of absence for three days, July 24, 1893.

Asst. Surgeon J. W. BRANHAM, to proceed to Brunswick, Ga., for temporary duty, July 25, 1893.

Asst. Surgeon E. K. SPENCER, granted leave of absence for fifteen days, July 25, 1893.

Asst. Surgeon EMIL PROCHAZKA, relieved from duty at Ellis Island, N. Y., and ordered to report to medical officer in command, New York City, July 29, 1893.

LETTERS RECEIVED.

The Journal of the American Medical Association

VOL. XXI.

CHICAGO, SEPTEMBER 9, 1893.

No. 41.

ADDRESSES.

FIRST PAN-AMERICAN MEDICAL CONGRESS.

AN ADDRESS DELIVERED BY THE PRESIDENT OF THE CONGRESS.

WILLIAM PEPPER, M.D., LL.D.

PROVOST AND PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE
IN THE UNIVERSITY OF PENNSYLVANIA.

In the City of Washington, D. C., September 6, 1893.

Gentlemen of the First Pan-American Medical Congress:—This occasion is an unique one, and the thoughts which force themselves on the minds of all of us are, I am convinced, so similar that the briefest greeting might well seem the most fitting address. But when I reflect that I stand here to represent the original committee appointed in pursuance of the resolution which was adopted unanimously on May 5, 1891, at the meeting of the American Medical Association, and that this resolution extended a cordial invitation to the medical profession of the Western Hemisphere to assemble here in a Congress, I realize the unusual dignity of the duty I must discharge. If anything could add to the dignity of this assemblage, which for the first time asserts formally the organic union of the physicians of all America, it is the fact that the Congress of the United States, impressed with the importance of our proposed meeting, passed a joint resolution (July 18, 1892), requesting the President to extend those invitations in response to which we welcome the presence here of official delegates from all the governments of the Western Hemisphere. In like manner are the several States of our own Union, the principal municipalities, and many of the leading educational institutions, both of North and South America, represented officially. You will not, then, think it strange that, called upon to address such an assemblage in this Columbian year, it should seem less fitting to dwell upon any technical topic than to turn our thoughts to the state of this continent and of its aboriginal inhabitants at the time of its discovery by Columbus, and to the obstacles which opposed him and the great men who completed his work. For these have had a bearing on the racial developments which have since occurred here, and should be held in mind in any estimate of the progress we have made during the subsequent four centuries. The state of medical science in Europe at the time of the discovery, and the spirit which has controlled its subsequent course, are fitly to be studied in connection with what we have accomplished during the same period and with the opportunities which present themselves to us at this time.

GENERAL RECOGNITION OF THE IMPORTANCE OF THE MEETING.

The recognition of the appropriateness and importance of this great meeting has been immediate and

universal. International although it is, the basis of its organization and the special features which mark it, remove all possible suspicion of an imitation of, or of interference with, the great International Congress whose successive meetings form a crescendo scale of scientific and administrative triumphs which the medical profession of the world regard with justifiable pride.

Our executive committee, and our efficient general secretary to whose unselfish energy and masterly powers of organization we owe a great debt of gratitude, studiously avoided the possibility of any such interference, by delaying the selection of a date for our meeting until that of the Congress at Rome was announced, and by then adopting a date which not only permitted but encouraged the presence later at Rome of those who should gather here. I can only add my deep regrets that the unhappy re-appearance of cholera in Southern Europe—striking example as it is of the urgent importance of the very work which calls us together—has necessitated a postponement until next spring; a postponement which, however, there is no reason to fear will lessen the complete success of the meeting on its newly-announced date. The International Medical Congress is, indeed, a splendid demonstration of the solidarity of the profession and of the world-wide scope of the objects we pursue.

This Congress represents much more, however, than our common interest in medical science and the common feeling of brotherhood which animates the entire profession. It is, indeed, it always has been, and forever may it so continue, the glory of the medical profession that their allegiance is one and undivided, for their service is solely in the cause of truth and humanity. Dynasties have risen and crumbled; the map of the world has been changed times almost without number, but the march of medical science through the ages has been ever onward and upward toward those lofty goals—the prevention of disease, the relief of suffering, the improvement of the race.

For us who meet here there is all of this glorious recollection and animating purpose, and there is much more to unite and to inspire us. We meet under the shadow of giant conceptions, as old as Aristotle, which agitated the minds of the great thinkers of antiquity, and were but slowly approaching a definite form when the sublime faith and genius of Columbus solved the problem of the globe.

It is true that this vast American continent, with its sixteen million five hundred thousand square miles of territory, already numbers one hundred and ten millions of inhabitants, embracing all types of human life, and many varieties of political organization. But all that has yet been accomplished is but the feeble beginning of the development which awaits us. When Canning secured the recognition of the republics of South America, he boasted that he had

called the New World into existence to redress the balance of the Old, and yet the luminous suggestions of Franklin, of Bolivar, and of Blaine as to the political and commercial relations of the countries of the western hemisphere are still only prophecies which must long await their fulfillment.

The destinies of nations are slowly evolved, and occurrences which fill the horizon of a generation appear to the broad gaze of history as mere features in the great panorama of the ages.

HISTORICAL REFLECTIONS.

Even a period of four hundred years is but a fraction of the history of Spain, of France, of England. Yet four hundred years ago this entire continent was not only undiscovered and unknown, but its very existence was unsuspected save in the ingenious speculation of philosophers. We recall the familiar but ever interesting lines of Seneca:

*"Venient annis secula seris
Quibus Oceanus vincula rerum
Laxet, et ingens pateat tellus,
Tiphys que novos detegat orbis
Nec sit terris ultima Thule"*—

and do not marvel that their strain of glowing conviction should have led Columbus to write them out twice over in his "Profecias." But all the same, this new world lay shrouded in the obscurity of the great Sea of Darkness, cut off, as we have since learned, from the known inhabited world, by changes wrought in remote geologic eras, and waiting the fullness of time which should lead the inspired genius of Christopher Columbus to seek the east by sailing west. We now know that in his quest of a western passage to Asia he reached the eastern shore of this continent on October 12, 1492, but even to the time of his death, on January 20, 1506, neither did Columbus nor any voyager or writer have any conception of the vastness and real significance of his discovery. All that the geographical knowledge of the day enabled them to grasp was the belief that Columbus had found a new route to the Indies by sailing west. Within a few years, however, the daring sailors of Spain and Portugal, of Italy and of England, pushed their voyages along the coasts. The astonishing discoveries of Americus Vesputius on his celebrated third voyage in 1501-02, when between Lisbon and the Island of South Georgia he traversed an arc of ninety-three degrees, led him to apply for the first time to this continent (it really was South America of which he spoke) the title of New World (*Mundus Novus*). It concerns us not to consider further how, by no intent or design of Vesputius, portions of South America at first, and later the entire continent, came after his death to be named after him. Yet when a few days ago I held in my hands the little quarto published in 1507, in which Professor Martin Waldseemüller, of the College of Saint Dié in Lorraine, first suggests the name America, in utter ignorance that the coast explored by Vesputius was continuous with or even related to the land discovered by Columbus, I could not help smiling sadly at the frantic and fruitless efforts we make to secure immortality by our petty observations, while here Fame, in strange whimsy, threw her laurels for the greatest discovery ever made around the head of one who neither had nor preferred a claim to it.

WHAT GEOLOGY AND PALEONTOLOGY HAVE TAUGHT.

Geology and paleontology have taught us that this

so-called New World is in reality, in a scientific sense, better entitled to the name of the Old World. The oldest known strata have their widest development on its surface, and animals, such as the horse, which are said to have been introduced after 1492, are shown to have had their original habitat here, and to have migrated hence to Europe, so that Cortes and Pizarro only reintroduced them to their former home. It is more important to recall the fact that the entire stretch of North and South America was, at that date, 1492, peopled more or less thickly with the descendants of tribes who had resided here from very remote antiquity. A high authority assures us that the number of these aborigines was probably from twelve to fifteen millions, and in spite of considerable differences in physical appearance, as between the Iroquois of New York and the Aztecs of Mexico or the Incas of Peru, in dialect and habits, it is generally conceded that this vast aboriginal population, of North America and South America alike, with the exception of the Eskimos, belonged to one great race of Red Men.

Eskimos and Red Men alike seem to have migrated to our continent at one time, or more probably in successive waves, in the remote past, either when the northwest corner of America was joined to Siberia by the elevation of the area now known as Bering Sea, or when the lofty submarine ridge which now passes from France to Greenland was elevated so that it would be possible to travel on foot from Europe to America. If the attempt be made to decide at what period of geologic time such immigration occurred, and whether in one great migration, or, as seems most probable, in successive waves, problems of extreme if not insurmountable difficulty present themselves.

The aborigines who were living on this continent at the time of its discovery by Columbus presented, it is true, considerable differences in the stage of development they had reached, as well as in their language and even in their appearance. There are long intervals of social development evident between the squalid sty of the California savage, the log house of the Iroquois, and the great structure of the Zuni, of Tlascala, or of Uxmal. Yet in them all can be demonstrated an underlying principle of adaptation to a certain mode of communal life such as all American aborigines are believed to have practiced. All attempts to distinguish the existence of special races, as of the mound-builders, have broken down in the light of critical study, and the powerful arguments of philology confirm the results of zoological study as to the essential unity of the American red race. The tribes in different parts of this vast territory certainly presented marked differences in physical appearance, and our ethnological collections show that as regards size and weight of frame and shape of skull considerable variety existed among them. But all possessed the cinnamon-colored or copper-colored complexion, the high cheek bones and small, deep-set eyes, the straight black hair, with scanty or absent beard; and the conclusion of the most competent authorities is that no sufficient differences, physical, linguistic, or social, existed to invalidate the evidence in favor of the unity of the race.

Fortunately we are not called on to attempt to read the geological record. For our purpose it is indifferent whether all the relics of the ancient

Americans are of the neolithic type, or whether the apparently plausible claim be ultimately established that paleolithic remains are also found in various places. This at least we know, that the soil and climate had shown themselves favorable to the development of a population already numerous, vigorous, hardy and enduring, and brave and warlike, though often cruel, and evidently advancing in social development, though at very different rates at different localities. Ignorant as we are of their primitive origin, it is doubtful if the most earnest advocates of the monogonist view that all mankind was originally descended from one pair, will urge that our aborigines were descended from a single couple, or even from a few boat-loads of Asiatics accidentally carried to our Pacific coast or that we shall hear again the arguments drawn from the many striking resemblances between the myths, languages, customs, or hand-wrought objects of the aboriginal Americans and of various Oriental nations. The surprise which, I am sure, all of us have experienced at these resemblances must be checked by these two thoughts so well expressed by Fiske and by Lubbock respectively, that one of the most important lessons impressed on us by a long study of comparative mythology is that human minds in different parts of the world, but under the influence of similar circumstances, develop similar ideas and clothe them in similar forms of expression; and again, that different races in similar stages of development often present more features of resemblance to one another than the same race does to itself in different stages of its history.

TREATMENT OF THE ABORIGINES.

An immense amount of sympathy has been expended upon the cruel treatment of the American aborigines by the European invaders. Of course, it was the sad old story, so often repeated, whenever a better armed and more highly civilized power has come into conflict with a primitive, ignorant, and ill-armed people. Over the ghastly picture of Indian slavery one would indeed wish to draw a veil, though its darkest shadows are relieved by the splendor of the character and labors of the illustrious Las Casas, and by the enlightened actions of those great men, Emperor Charles V, Pope Paul III, and Cardinal Ximenes. But it is a romantic extravagance to deplore the destruction of any system of government or society which existed in 1492 in any part of the continent. If the present state of the native Indian population in North and South America is far from satisfactory, and fails to fulfill the promise shown, especially in South America during the first century after the conquest, may this not fairly be attributed to unwise legislation by the ruling nations, to the absence of continued, effective religious instruction, and to the base cupidity which has led us to promote the fatal passion for stimulants, so common among barbarous people? There seems no sufficient evidence to make us lose hope that the remains of the aboriginal Americans may, under more wise and equitable treatment, gradually develop into useful citizens of our republics, and be capable of wholesome assimilation with the body of the population.

It is easy to assert and hard to disprove that the development of the red race on this continent was progressing slowly prior to 1492. As a matter of fact, we do not possess the data, either about their

early history or about the primitive condition and rate of development of any of the more civilized races, to permit us to institute a comparison. Our earliest knowledge of the ancient Egyptians, for instance, reveals them living in a state of civilization already advanced at least a full ethnical period beyond that even of the Aztecs. How many centuries had elapsed while the successive stages of savagery and barbarism were passing in Egypt can never be even surmised. There seems no reason to doubt that, had America not yet been discovered, there would have been going on here for the last four hundred years a slow and irregular approach to a higher social condition. There certainly is no doubt that during and since the conquest many sad mistakes, and not a few atrocious crimes, have been perpetrated in the name of civilization and of liberty. But, on the whole, the student of history is forced to admit the enormous advantages which have resulted from the conquest, by Europeans of the fifteenth and sixteenth centuries, of tribes the most advanced of which were still in a very primitive state of civilization. I have ventured upon this rapid sketch of a familiar subject because it is well that we should be clear in our comprehension of the conditions which existed in America four hundred years ago, when the start was made to introduce the European races and civilizations.

TWO CENTURIES REQUIRED TO DEMONSTRATE THE MAGNITUDE OF THE DISCOVERY OF AMERICA.

We meet here to-day to represent what these have accomplished in their new environment during these four centuries in regard to certain highly important subjects. We cannot fail to be interested in considering what scientific acquisitions in these branches were actually brought here, what disadvantages were to be contended with, how far our progress may be regarded as satisfactory, what great questions there are which concern us all deeply, and in what lines of research and work we may unite for the common good, and for the greater advancement of science.

The words graven on the tomb of Ferdinand Columbus in the cathedral at Seville: "To Castille and Leon, Columbus gave a New World," are indeed true, but they do not express the whole truth. John Fiske well says: "The discovery of America may be regarded in one sense as an unique event, but it must likewise be regarded as a long and multifarious process. The unique event was the crossing of the Sea of Darkness in 1492, and no ingenuity of argument can take from Columbus and from Spain the glory of an achievement which has, and can have, no parallel in the whole career of mankind. It established a true and permanent contact between the eastern and western halves of our planet, and brought together the two streams of human life that had flowed in separate channels ever since the glacial period." But to demonstrate the magnitude of this discovery, to determine the physical features of this Western Hemisphere, to plant firmly the seeds of European civilization, demanded the heroic exertions of two full centuries. Not Spain alone, but Portugal, Italy, France, England, Holland, Denmark, Russia, played their part, and the names of Cabral and Pinzon and Magellan, of Cortes, Balboa, and Pizarro, of Ponce de Leon and De Soto, of Champlain and LaSalle, of

Drake, Hudson, Baffin, Davis and Bering, must remain associated forever with this stupendous and progressive work of discovery. Not until 1806 was the last step taken by Lewis and Clark, who then succeeded in crossing the continent of North America from east to west, and thus completed the task undertaken by Champlain in 1608. And if the mere study of the outlines and dimensions of America occupied two centuries, what are we to say of the far greater obstacles opposed to the colonization of the vast territory, and to the determination and establishment of suitable forms of government, and of harmonious relations between the numerous States and countries into which America soon came to be divided?

The older political systems of Europe seem to require still the assistance of considerable artificial support, and their occasional disturbances are of a decidedly unpleasant character. Is it strange that some of us still have our little unpleasantnesses at home or with our neighbors, which indicate that the education of our people is as yet woefully imperfect in those things that most nearly concern their welfare? Of this, at least, we may be sure, that all that promotes free intercourse among us helps on mightily the solution of these hard problems. It is a true saying that to know is to excuse, and, more than this, in regard to nations if not strictly in regard to individuals, it may be added that to know is to love. We turn with quickened interest to the sage advice of the illustrious Franklin, who, in 1749, embodied in his plan for the organization of the University of Pennsylvania an earnest advocacy of the thorough teaching of the Spanish and Portuguese tongues as likely to hasten the development of those close reciprocal relations which he foresaw would inevitably arise between the countries of the two Americas. The spirit of the age as it embodies itself in our educational systems and in our literature, the giant forces of steam and electricity, as they link together the most distant points of our territory, are working inevitably together for the enlightenment, the elevation, the better mutual understanding, and the more cordial relations of all of us.

The year whose four hundredth anniversary we now celebrate found the world stirred as never before. A work of tremendous importance for the future of the human race had been going on amid the gloom of what are often called the Dark Ages. The more closely this period of absorbing interest is studied the more do we appreciate the magnitude and the necessity of the changes effected during those centuries in preparation for the splendid activities of the Renaissance. The mission of the Middle Ages had been really, though not obviously, a cosmopolitan one, and it was fitting that the noblest achievement of the Renaissance should be the discovery of America. The barriers between nations had been lowered, and there had been going on the process of blending and interpenetration which was soon to be extended to this Western Hemisphere with such large results. The protest against mere dogma in religion and in philosophy; the revolt against usurped and abused absolutism; the demand for light and knowledge and the common rights of humanity, these awakened then to be stifled no more, but to swell forever in larger utterance until they shall, in some yet distant golden time, announce universal liberty under equitable laws and universal

peace through arbitration. It is not for us to taunt the glowing expectations of the men of 1492 with their long-postponed fulfillment. It ill becomes us of to-day to speak in other than tones of humility when across the brightest spots of the vaunted civilization of the close of the nineteenth century after Christ there still fall so many dark shadows lingering from the deep medieval night.

How each generation turns aside with the restless impatience of children from the lessons of the past, and shuts its eyes to the truth which inexorable history calmly shows, that long periods of time are required for the accomplishment of each great advance in religious, or political, or social, or scientific truth.

Yet though we smile somewhat sadly as we read the bursts of enthusiasm so plentiful at that time, we dare not challenge the fitness of that grand name, the Renaissance, to the age which, through its mighty discoveries and the master minds who used them, diffused among the nations the new conceptions of the earth and the skies, of the church and the state. Only the pity of it that such long centuries of travail must ensue between this implanting of the seed of religious and political liberty and the mature growth for which we still wait.

THE DISCOVERY OF AMERICA, THE DIVIDING LINE BETWEEN
THE MIDDLE AGES AND THE MODERN ERA.

In no respect may the discovery of America be regarded as the dividing line between the Middle Ages and the Modern Era more truly than in regard to medical science. In spite of the prodigious learning of the most distinguished Arabian and Jewish physicians, such as Avicenna, the Prince of Physicians, of Albucasis, of Avenzoar, the Wise and Illustrious, of Maimonides, their medical science was too largely speculative and philosophic. Great universities were established, some of which, as those of Bagdad and of Cordova, possessed regal revenues and magnificent libraries. Numerous hospitals were founded, of which the large and wealthy one established at Cairo in 1283 merits special mention. But the outcome of this long dominion of the Arabs and the Moors, so far as concerns medical science, was merely a marked advance in chemistry and pharmacy, the introduction of many new remedies, and the advocacy of the union of the natural sciences with medicine. Their chemistry was tinctured strongly with alchemy, their clinical teaching was elementary, their diagnosis and treatment lacked the true Hippocratic force and directness.

The endless speculations and metaphysical discussions of the schools had shown that it was not that way true progress lay. Unaided observation had scarcely gone further in eighteen hundred years than the point to which the immortal Hippocrates had carried it. True medical science, which could not progress without precise methods and instruments of precision, was forced to wait until from very different quarters came the development of the natural sciences and the era of exact experimentations which alone rendered them possible. Harvey's immortal discovery of the circulation of the blood was not announced until 1616, and his almost equally important and epoch-making discovery of the origin of the higher animals from the egg was published in 1651; yet it may be safely asserted that the work of this modest and truly scientific Englishman did more to advance medicine than all the labors of all

the schools from the days of Hippocrates. Not only were the facts demonstrated of infinite importance, but his method of patient, exact observation and experimentation until the truth was developed by cautious induction marks the introduction of a new era, and stamps Harvey as the father of modern medicine.

Galileo first indicated the use of the thermometer in medicine about 1595. Sagredo, of Venice, improved it in 1613, and Sanctorius, in 1625, urged its importance in the study of disease forcibly, but as yet ineffectually. Just as the astronomer, Galileo, gave us the first rude thermometer, Kepler, another illustrious astronomer, gave, in 1604, the first record of an accurate count of the human pulse. But so slowly did the importance of this datum in the study of disease impress the medical profession that the acute Sydenham, who lived until 1689, nowhere mentions a single pulse count. It is hard to find anything which illustrates better the radical difference between the spirit of medieval and of modern medicine than the vast mass of obsolete literature upon the pulse, loaded with fanciful speculation and super-refined subtleties of description, and yet wholly deficient in the only features which would give practical value to the study. What progress in exact medicine could be made without chemistry? Yet scarce any development in this branch occurred between the eighth and seventeenth centuries. And it was Boyle, the father of modern chemistry (not born until 1627—died 1691), who first succeeded in freeing from the trammels of alchemy this noble science. Not until the end of the seventeenth century did the value of quantitative analysis begin to be appreciated. Lastly, it was not until 1590 that we hear of the first compound microscope in the hands of Jansen.

Meanwhile the gross superstitions, combined with a blind dependence on the great authorities of antiquity, and especially on Aristotle and Galen, which had so long dominated medical science, yielded slowly to the growing light of positive knowledge. Fine-spun subtleties, drawn from metaphysical speculation; the fantastic notions of alchemy and astrology; the rank growth of impostures which flourished in the soil of ignorance, and the bigotry which placed every organ under the charge of a special saint and conjoined with every remedy a special form of supplication, still marked medical teaching and medical practice. But the bold, fearless, investigating spirit of the sixteenth century did its work for medicine as it did for other great matters. Vesalius (1514-1564) and his contemporaries created accurate anatomy. Paré (1500-1590) stamped imperishably on surgery the influence of his genius and lofty character. Paracelsus (1493-1541) hurled the shafts of ridicule and invective against the groveling subserviency to ancient authority, and did a rough but important stroke of work toward the emancipation of the medical mind. The grand old Hippocratic method of careful observation and cautious reasoning was reasserted, the unproductive philosophy of Galen and his Arabian worshipers was discarded, and at last there began to emerge from the darkness of so many centuries modern medicine, the medicine of loyalty to Nature and revolt against mere human authority; of reverent skepticism and reasonable faith; the medicine of scientific experimentation and of humane vivisection, that insisted upon knowing

the causes of disease and that looked to hygiene as its noblest expression.

The history of European medicine for more than three hundred years is a record of which we may well be proud, when the enormous obstacles to progress are held in view. It is not necessary to remind this audience of a single one of its great triumphs. Vesalius and Paré, Harvey and Sydenham, connect themselves with Richat and Lænnec, and Hunter and Jenner, and Pasteur and Lister, and Virchow and Koch, and the torch of genius is passed down the line of these immortals and lights up the ages with the splendor of their achievements. But it is sad to reflect upon what has been done as contrasted with what might have been. The dense ignorance of rulers and masses on scientific questions, the slow progress of sound, useful education among the people, the huge claims of imperialism and of militarism, the wanton waste of luxury, have retarded research, have left but paltry sums available for the diffusion of knowledge, have hindered the embodiment in legislation and in actuality of much that would help the healing of the nations. It is an odd commentary on the vaunted civilization of to-day to contrast the sums doled out by the most enlightened governments of Europe for the promotion of higher education and original research, or for the suppression of preventable diseases, with those lavished on the vast hosts of armed men and the huge fleets of unwieldy armored ships deemed necessary for the maintenance of peace and order.

THE DOCTRINES OF DARWIN.

Within our own day we have seen the announcement of the grandest generalization reached by the human mind, in this century at least, and advanced in the most philosophic and inoffensive manner, received with a burst of intellectual skepticism and of religious intolerance, which showed that the old forces against which the Renaissance protested, and still protests, are yet alive, though happily shorn of most of their power. The marvelously rapid spread of the illuminating doctrines of Darwin, and their incorporation in the thought and speech of the world, and in the teachings of the churches, may indeed be pointed to as the crowning intellectual achievement of the nineteenth century.

PROGRESS OF MEDICAL EDUCATION IN AMERICA.

If the actual progress of medical science was slow in Europe during the years which followed that *annus mirabilis*, 1492, surely no word of reproach may be uttered against the early settlers in North and South America, because, amidst their heroic efforts to conquer this vast continent, it was long before they found time or energy to devote to the cultivation of that practical and essential subject of medical science. It is true that in 1551 Charles V founded the University of Lima, in Peru, and in 1553 the University of Mexico. Yet it does not appear that medicine was taught at these universities until a little prior to 1700.

In North America, although Harvard College was founded in 1636, the title of university was first applied to the University of Pennsylvania, which in 1765 established the first school of medicine in the United States. The scattered handfuls of early settlers on our shores had, indeed, problems facing them more urgent than the promotion of science,

They differed as widely in their motives for undertaking the appalling task of conquering and colonizing America, and in their fitness for the work, as they did in their nationalities. Separated widely from the mother countries, hampered very often by unwise and vexatious interference from the home governments, they waged war against the powerful tribes of aborigines who swarmed over the country, and against the no less serious obstacles of untried climatic and political conditions. Bloody warfare raged promiscuously and disease was rife. We have seen that the work of mere preliminary exploration occupied two centuries. The close of the third century found the early struggles approaching a successful ending, only to be followed by violent political changes, not accomplished save by long and costly wars. The English conquest of Canada in 1759-60, the achievement of independence by the United States in 1783, the establishment of the independence of the South American republics in 1810 and the ensuing twenty years—these are the events from which the future historian will date the Renaissance or the Decadence in America, and to which reference will always be made in estimating our capacity for progress in politics, in literature, in art and in science.

For a long time it seemed even to friendly critics that the new races which strove for a foothold on American soil were unlikely to thrive as vigorously as in their accustomed habitats, and the impossibility of developing a genuine and lasting American type was freely asserted. To those of us who have considered this point with anxious care the last two decades have brought results that put to rest all apprehension. Whatever may be the future changes in the political organization or relations of the countries composing America, it is a demonstrated fact that the European race in America, which already numbers over one hundred millions, will show no decline in vigor or in energy, in physical or in mental strength. It is not on account of mere bigness in material achievement that we point to the millions who fought in the great civil war; or to the one hundred and seventy thousand miles of railroad in the United States—almost as much as in all the world besides—and the \$10,000,000,000 of capital invested, and the army of nine hundred thousand employees; or to that tremendous structure, the Canadian Pacific railroad; or to the plans now under consideration for developing a continuous railway system for the entire continent, from Montreal or Puget's sound to Buenos Ayres. It is, even more, as evidences of large imagination, of courageous resolution and dauntless tenacity of purpose, and of enormous power of physical endurance that we value the enterprises which have subjugated this continent so swiftly and are hastening its commercial consolidation. We may be assured that countries which have shown such sturdy love of independence and resistance to outside interference, which have displayed so much sagacity in adapting their political constitutions to their peculiar conditions, which liberate and enfranchise all who dwell within their limits and afford to all an equal chance of advancement, will work out their destinies to far larger and wiser plans of friendly cooperation than we can now foresee.

Turgot, in his memorable address in the Sorbonne, well declared: "Tous les âges sont enchaînés par une

suite de causes et d'effets qui lient l'état du monde à tous ceux que l'ont précédé." The discovery of America depended on the operation of causes which can be traced back many centuries. The present condition of our continent, four hundred years later, is the result of the action and reaction of mighty movements which involve every country of the world. Here is the new and probably the last great place of gathering and intermixture of all nations. Here, as nowhere else are to be studied with all the aids of exact science the problems of ethnology and sociology. Here are to be worked out to the best advantage the problems concerning the relations of man to his physical environment; and the demonstration that in spite of the apparent magnitude of the powers of nature, and in spite of the admitted influence of climate and physical condition upon the progress of civilization, the powers of man for intellectual and social advancement are incalculably superior.

In all of this work a large share must devolve upon medical men, and fortunately our position in America is one which will enable us to work together with good effect. The high average intelligence of our people will make them prompt to appreciate results of solid utility or scientific value. The enormous wealth, present and prospective, of this continent should readily be diverted more and more bountifully to the promotion of learning and research—if, as may be trusted, we shall strive more and more after peace among ourselves and abroad.

We shall never cease to be proud of our lineage, or to acknowledge the immense debt we owe to Europe. Its languages are ours; its glorious past is part of our heritage; its mighty names in art and philosophy and science are household words with us; its rapidly advancing civilization incites us to loftier efforts. But the balance between the Old and the New Worlds is being redressed.

All know how the examples of our young and vigorous communities have supplied and fed the infectious principles of political liberty and of social equality. In every struggle for the rights of man, from the terrible but beneficent drama of the French revolution down to the present hour, our example and our assistance have been invoked.

—SERVICES RENDERED BY AMERICA TO MEDICAL SCIENCE.

I cannot detain you by an enumeration of the services already rendered by America to medical science. Almost immediately after the discovery, important contributions to pharmacology were announced, chiefly from South America, and from the introduction of guaiacum in 1508, until now, these contributions have become more and more frequent. The entire medical world was agitated during the latter half of the seventeenth century by the struggle over the merits of cinchona bark, introduced into Europe in 1640, by Juan del Vego, and no more convincing tribute can be adduced as to the value of medical and sanitary science than the prominent place occupied by malarial diseases in the general and medical literature of the seventeenth and eighteenth centuries as contrasted with the feeling of impunity with which they are now regarded. Among the results which may be anticipated from this meeting is, I trust, the adoption of some well-considered plan for systematic conjoint study of our American remedies and their pharmaceutical preparations, looking to their scientific classification, to

greater uniformity in their preparation, and ultimately to a single pharmacopœia for the entire continent.

The introduction of nitrous oxide (1844) and of ether (1846) into medical practice, with which the names of Wells and of Morton are so honorably connected; the establishment of the operation of ovariectomy by McDowell of Kentucky, upon a secure scientific basis—these and hundreds of other achievements of lesser brilliance are too familiar to need mention. Every one knows now how superfluous it is to say a word in defense of American literature, and certainly we who know how powerfully the opinions and practice of medical men in Europe and throughout the world are influenced by American writings may view our position with some complacency. Yet a survey of what America is actually contributing to medical literature shows clearly how far we are behind the nations which lead in medical thought. In the year 1879 Rupprecht's *Bibliotheca* gave as the total number of new medical books, excluding pamphlets, periodicals and transactions, 419, divided as follows, viz.: France, 187; Germany, 110; England, 43; Italy, 32; United States, 21; all others, 26; and for 1891 I find the same *Bibliotheca* gives the total number as 1,063, divided as follows, viz.: Germany, 360; France, 243; Great Britain, 141; United States, 80; Italy, 78; Austro-Hungary, 70; Spain, 24; and other countries (chiefly Switzerland and Denmark), 67.

On the other hand, in the more ephemeral forms of medical literature the figures are very different. I have had a careful count made of the volumes of medical journals and transactions filed in the library of the Army Medical Museum at Washington with their respective places of publication, and from this it is clear that of these classes of medical literature there were in 1890 and in 1891 published in America (including Canada, the United States and Latin America) about twice as many volumes as in Germany or France, and fully three times as many as in Great Britain.

Of course we must not forget the fact that in the hurry of our life of to-day many observations and investigations of great value are published in journals, instead of being reserved to become part of more serious and complete volumes. But it will not be doubted, I think, that the great excess of medical journals in America, as contrasted with the comparatively small number of new medical works, is entirely consistent with the admitted leadership of Germany, France, and Great Britain in medical science. The fact that during the past twelve years Germany has risen from a place in this list second to France, 110 as against 187 in 1879, to the first place at present, with 360 new medical works in 1891 as against 243 published in France, speaks eloquently of the strenuous effort with which newly-united Germany is straining forward in science as in other fields. The truth is that the apparently extraordinary number of medical journals in America is due chiefly to a substantial reason, and one which influences equally the existence of very numerous medical schools and medical societies. The vast extent of territory, and the relatively sparse population render it impossible to serve the country with as low an average of medical men, schools, societies, or journals as is possible in more densely-populated countries. As to other and less satisfactory reasons which have operated, especially in the United States,

to produce a great growth of ill-equipped medical schools and of poorly-supported new journals it is not necessary to speak here. Indeed, the rapid rise in the standard of scientific requirements, both of medical men and medical literature, and the increasing appreciation on all sides of the fact that the higher medical education is the true interest, both of the profession and of the public, is accomplishing the much-needed work of checking the ill-considered establishment of new medical enterprises, and of stimulating those in existence to more earnest life and more lofty aims.

So true is this in regard to our medical journals, that no one who has occasion to consult regularly the files of any number of them, can fail to be struck forcibly with the steady and decided improvement in the tone of their management and in the scientific quality of their contents.

This Congress meets at a period of peculiar and critical interest in medical education, and I am glad to say that for the first time in the medical history of the United States we may feel proud to have such a meeting convened here, and to invite a close examination of our educational standards and facilities. I should fail in courtesy and in candor alike, were I not to acknowledge the great value of the example which has been so consistently set by Latin America and by Canada in the maintenance of a high standard of qualifications for medical practitioners.

Fifteen years ago the medical profession of the United States arraigned severely the management of their over-numerous medical schools. While Canada then exacted a reasonably strict entrance examination and a course of medical study extending over four years, with one session of six months in each year, and while every country in Latin America exacted a collegiate degree or a rigid entrance examination, and a course of medical study extending over six years, it was the general custom with the medical schools of the United States to grant a diploma conveying the full right to practice medicine to applicants who had been admitted without preliminary examination, and had attended without term examinations two courses of lectures covering about five months, and had passed a single and final examination conducted by their own teachers, whose emoluments were derived solely from the fees of such students. This discreditable prostitution of a great educational trust had been gradually brought about by large causes upon which I may not now comment. But it is with justifiable pride that we may point to the admirable and sweeping reforms that have since been instituted. It remains true that the laws of many of the States allow charters for medical schools to be secured without any guarantee of the standard of education that shall be maintained. But the awakened sentiment of the profession and of the community has, in a rapidly increasing number of the States, insisted that medical graduates before being admitted to practice shall pass a State examination conducted by an impartial board of examiners appointed by the governor. The medical schools, to their honor be it proclaimed, have, with few exceptions, been foremost in the struggle to secure this wise and beneficent legislation. They have done much more. In advance of these laws which will ensure a far higher standard of medical qualifica-

— Regular schools, 65; Homeopathic, 11; Eclectic, 4; total, 80, in 1877.

tions in the States fortunate enough to be so protected, the faculties of a number of the leading schools have forced their standard up at first to three years of obligatory study, and now to four years of eight months' study each, with a carefully graded curriculum and with strict examinations before entrance, at the close of each term, and finally before graduation.

When we recall that this has been done without the slightest governmental aid; and further that, owing to the prevalent view that medical schools have been sources of large profit to their faculties, the streams of private benefaction had not yet been directed in their favor, you will appreciate the high sense of duty and the devotion to science which have led these faculties to assume greatly increased labors with an expectation of considerably diminished remuneration owing to reduced attendance of students and to augmented expenditures.

The committee of arrangements of this Congress has wisely provided for a tour of inspection of some of these institutions. It is trusted that all of our foreign delegates, and as many as possible of the members of this Congress, will avail themselves of this opportunity to examine the equipment of some of our leading medical schools. They will be gratified to find in hospitals, in laboratories, and in libraries and museums alike, facilities which bear comparison with those of Europe. They will find an arrangement of studies and, above all, an organization for the conduct of daily, thorough bedside instruction in all branches of medicine, which leave little to be desired. It is easy to foresee, as another of the desirable results of such meetings as this held successively in various parts of America, such increased acquaintance with and confidence in our respective methods of medical education and medical treatment as will retain on our continent many of our students and many of our invalids who have been in the habit of going farther to fare no better.

A broad field opens before us for the study, with the aid of collective investigation, of the distribution and course of phthisis and rheumatism and other important diseases as influenced by race and locality. The endemic fevers, other than malarial and typhoid and yellow fevers, which are said to prevail in various parts of North and South America, have long demanded systematic investigation to complete the study which the illustrious Drake began. We shall now have the opportunity of studying, equally by means of collective investigation, the relative effects of various climates on the numerous races now represented in America, and of determining more accurately the scientific and practical questions connected with our extensive series of health resorts, which embrace the finest examples of every type. There are, indeed, none of the Sections provided for in this Congress from whose work more valuable results should follow than from those on medical pedagogies, on hygiene and climatology, and on quarantine. It was a sense of the urgent importance of these latter subjects, especially at the present time, and of the valuable results sure to follow their consideration by such a body as this, which led the government of the United States to extend the cordial invitation which has been uniformly accepted on the part of the Pan-American governments. I feel that by this action there has been secured for the subject of hygiene and State preventive medicine a formal recognition never before accorded on

this continent, and one which must surely be followed by the willingness of the respective governments to use their influence to secure the enactment and efficient administration of proper legislation in accordance with the recommendations of this body of eminent experts.

PROFESSIONAL ORGANIZATION NECESSARY.

When the International Medical Congress met in Philadelphia in 1876, the address on hygiene and preventive medicine, delivered by the distinguished Bowditch, himself a pioneer in sanitary science, was one of the most impressive utterances on that important occasion. The review there given of the work of the previous century in this country in sanitary science was not flattering, but with the fine enthusiasm which marked that gifted man he predicted the immediate opening of the grandest epoch yet seen in the history of medicine. His closing appeal must be quoted: "OUR PRESENT DUTY is organization, national, State, municipal and village. From the highest place in the national council down to the smallest village board of health we need organization. With these organizations we can study and often prevent disease." These stirring words were in accord with the spirit of the times and with the developments of science. When the brilliant discoveries of Koch brought to light the specific bacillus of tuberculosis and of cholera, and pointed out the scientific method to be pursued in similar investigations in the future, an unanswerable argument was provided against skepticism or indifference or official penuriousness. It required courage and showed rare breadth of view in Lord Palmerston to issue his celebrated reply to the presbytery of Edinburgh on the occasion of the threatened outbreak of cholera in 1853, in which he urged that the weal or woe of mankind so far depends upon the observance or neglect of the natural laws by which the affairs of the world are regulated, that if the local causes of disease were not removed before the return of the hot weather, the pestilence would be sure to return in spite of all the prayers and fastings of a united but inactive nation.

Much was accomplished, it is true, in preventive medicine between 1853 and 1876, when Bowditch spoke, but it is scarcely an exaggeration to say that the progress in the past twenty years has been greater than in the preceding twenty centuries. We have not, indeed, yet detected the specific poison of every infectious disease; even in regard to the familiar and much studied yellow fever, the latest publication of our distinguished Surgeon General, U. S. A., shows that this point is still unsettled. But the position of the whole matter is changed radically. Hypotheses have given way to facts. Every one now knows, or ought to know, that the most dreadful diseases are inseparably connected with definite organisms; that these organisms have special laws of development and distribution; that to destroy or exclude them is to avoid the disease, and that to tolerate conditions which favor their development is to encourage and invite the attack of the disease. When these simple, demonstrable propositions are considered in connection with such scourges as cholera and yellow fever, and typhus and typhoid fever, and scarlatina and diphtheria, and epidemic meningitis, it needs no further argument to prove the value and the necessity of quarantine, and of efficient medical inspection.

tion and protection. Nor does it need further argument to show the wisdom of establishing laboratories of hygiene at many points over the country, of equipping them amply with the ablest men and the finest apparatus, and of endowing them liberally, so that the search after the yet unknown causes of disease, and after the best methods to prevent the development of such causes as are known, may be prosecuted with ceaseless vigor.

It is easy now to get a hearing for these views, when public comfort is disturbed, the public purse threatened, and the public conscience awake and sensitive. At this moment our great commercial communities are reposing in confidence upon the sanitary measures adopted by our governments, in accordance with medical advice, for the restriction and exclusion of two dreaded pestilences, cholera and yellow fever. Recall with me the popular terror of last summer. Recall the hideous loss of life and the disastrous effects on commerce caused by former invasions of these diseases when the communities afflicted were smaller and less wealthy than are ours at present. We do not have to seek back to the Middle Ages for pictures of desolation wrought by infectious disease. Recall that tragic story of the great yellow fever epidemic in Philadelphia just one hundred years ago, as told by Rush. Try to estimate the result if cholera had effected a lodgment in New York city in July, 1892, and having found favoring local and climatic conditions, had, as on former occasions, spread its deadly germs to the north and south and west. The fair White City that was rising by that distant lake, under the magic wands of Art and Industry, would have been stricken with a fatal blow. No computation can well exceed the loss that would have fallen on this country. The entire people gazed with bated breath at the struggle waging in New York harbor, and universal thanksgiving arose when the dread invader was finally repulsed by the vigorous and sustained efforts of the sanitary authorities. That we, in America, are not to-day witnessing the aggravated recurrence of the epidemic, in accordance with unvarying precedent, can be due only to the continuance of these same efforts, reinforced with large authority, and aided by more efficient local sanitation. When this gratifying result is associated with the success which for some years has attended our efforts for the exclusion of yellow fever, no further argument can be needed to urge the adoption of such uniform measures as will for the future afford most sure protection against these diseases. These instances exhibit in the most striking manner the need and the value of the international sanitary agreements this Congress may do much to promote. But there will occur to all of us many other important questions to be solved only by earnest and united work. Nor can this work be accomplished until Bowditch's cry for organization is far more fully answered than it has yet been. Nothing but organization and coöperation, and, yet more, the establishment in the government of every civilized nation of a department of public health, will secure the continuous and forcible attention which the magnitude of this enterprise demands. There should be, and the day cannot be far distant when there shall be, in the cabinet of every government here represented, a secretary of public health, of rank, influence, and prerogative equal to that of any other cabinet officer.

Here, then, is the last and greatest service to be rendered to science and to the nation by our Congress. Our combined influence will be irresistible when used in advocacy of higher education; in carrying out large plans for the scientific study of our national life, as affected by social and climatic influences; in the adoption of remedies and remedial measures of demonstrated merit, and in the insistence upon a fuller recognition of the lofty function of preventive medicine. "Salus Sanitasque Reipublice, suprema lex." Let us acquire here a closer touch with each other, a deeper faith in our profession and its noble destiny, and a stronger determination to labor in brotherly coöperation for the loftiest ideals of service to science and the race.

ADDRESS TO MEMBERS OF THE PAN-AMERICAN MEDICAL CONGRESS.

BY BRIGADIER GENERAL GEORGE M. STERNBERG.

SURGEON GENERAL U. S. ARMY.

EXECUTIVE PRESIDENT OF THE SECTION ON MILITARY MEDICINE AND SURGERY.

Washington, D. C., Sept. 6th, 1893.

Gentlemen:—We are assembled for the purpose of discussing questions relating to military medicine and surgery; to consider what progress has been made in the treatment of camp diseases, and of gunshot wounds as a result of recent discoveries relating to the etiology of infectious diseases and of traumatic infections; to profit by the experience of those who have had experience in the care of wounded men upon the field of battle and of the sick of armies engaged in actual warfare; to deliberate as to the best methods of transporting the wounded from the firing line and of rendering them the immediate assistance which may be required to save life; to compare the injuries inflicted by firearms now in use with those which came under our observation when a larger bullet with a much less initial velocity was the missile which caused a majority of the wounds we were called upon to treat.

All of these questions are interesting to us as military surgeons and of vast importance so far as the victims of future wars are concerned. It is true that peace prevails everywhere in the new world; that a most friendly feeling exists among the republics of North and South America; and that the modern way of settling disputes between nations is by arbitration rather than by a resort to arms. But so long as armies exist and deadly weapons are manufactured it will be the duty of the military surgeon to be prepared to render efficient aid to those who fall in battle, and to give the victims of those "camp diseases" which sap the strength of armies the benefit of the most efficacious treatment.

A still more important part of the duty of the medical officer in garrison or in the field consists in the sanitary supervision of the command with which he is serving; for, without doubt, most of the sickness which prevails among soldiers, and especially among new levies of troops, is due to insanitary conditions, and is preventable to a greater or less extent according to circumstances. But the subject of military hygiene does not properly come within the province of this Section, and we simply refer to its importance *en passant*.

We are, however, especially interested in the subject of the transportation of wounded men from the

field of battle. And in future wars we will have to meet new conditions, arising from the use of weapons having an extremely long range and from the nature of the wounds inflicted by bullets of small caliber projected with enormous velocity. Men will be disabled in great numbers within very brief periods of time, and of those struck by these missiles a large portion will require to be promptly removed from the field of action, for a smaller proportion will be killed outright.

Under these circumstances it is evident that our organization for the purpose of rendering first aid to the wounded and transporting them to the field hospitals must be carefully considered, and that the most efficient service will require a corps of assistants especially trained for this duty.

This matter has already received the careful attention of medical officers in the United States army, and we have now an organization designed to perform these duties, with the assistance of "company bearers" who also receive special training with reference to first aid, litter drill, etc. In time of peace our enlisted men of the "hospital corps" perform the duties of nurses, cooks and attendants in post hospitals, and they are regularly drilled in the most approved methods of handling wounded men and removing them from the field of battle.

A manual of drill for the hospital corps has been prepared by a board of medical officers and approved by the secretary of war. It will shortly be published "for the information and government of the army and for the observance of the militia of the United States." A demonstration of the litter and ambulance drills, as directed by this manual, will be made by Major Hoff of the medical department of the army, English speaking secretary of this Section, who was one of the medical officers to whom the duty of preparing the manual was intrusted. After this demonstration I hope we may have a free discussion of the merits of the system, as compared with the older, haphazard way of caring for wounded men which prevailed during our civil war. There are many present whose experience upon the field of battle will enable them to judge of the advantages which are likely to result from system and previous training in handling wounded men; and also as to the practicability of carrying out, upon the firing line, the methods which have been adopted.

The results obtained by our military surgeons during the late war are summarized in the accompanying table, which has been prepared, at my request, by Major Charles Smart, Surgeon U. S. A., from the data on file in the surgeon-general's office. The table also shows the number of amputations and excisions made by medical officers of the army since the war and the percentage of mortality from the same. It will be seen that the mortality rate has been considerably reduced. This is no doubt partly due to improved methods of treatment, and especially to antiseptic surgery, although a considerable proportion of the operations made since the war were made before the general adoption of antiseptic methods, or under circumstances which did not admit of the strict application of these methods.

For the purpose of showing the enormous responsibility of the medical department of an army in time of war the following figures are given, showing the total number of cases treated in the armies of the United States during the late war, as given in

the "Medical and Surgical History of the War of the Rebellion." The figures relate to white troops only, and are for the period from May 1, 1861 to June 30, 1866:

TABLE SHOWING THE NUMBER OF AMPUTATIONS AND EXCISIONS OF THE EXTREMITIES DURING THE WAR OF THE REBELLION AND THE PERIOD 1866-1891, WITH PERCENTAGES OF MORTALITY.

	UPPER EXTREMITY.			
	During the War.		Since the War.	
	Number of Cases.	Percentage of Mortality.	Number of Cases.	Percentage of Mortality.
Amputations:—				
Shoulder	852	28.5	7	14.3
Arm	5,456	23.6	62	19.4
Elbow	36	8.4	1	1
Forearm	1,747	13.9	57	8.8
Wrist	68	10.6	10	1
Fingers, with or without metacarpals	7,842	2.6	830	.1
Total	*16,001	...	967	...
Excisions:—				
Clavicle or scapula, partial	80	2.7	5	1
Shoulder	485	84.8	1	20.0
Humerus	696	28.5	11	1
Elbow	624	23.7	5	20.0
Bones of forearm	986	11.2	7	1
Wrist	96	15.6	1	1
In hand	116	8.6	22	4.5
Total	3,485	...	52	...
	LOWER EXTREMITY.			
	During the War.		Since the War.	
	Number of Cases.	Percentage of Mortality.	Number of Cases.	Percentage of Mortality.
Amputations:—				
Hip	66	82.3	4	75.0
Thigh	6,229	53.8	63	41.3
Knee	189	56.6	7	1
Leg	5,432	32.9	87	20.7
Ankle	161	25.1	21	9.5
Partial of foot	1,548	5.7	182	...
Total	*13,655	...	364	...
Excisions:—				
Hip	66	88.6	6	33.3
Femur	175	69.4	3	33.3
Tibia	57	81.4	1	1
Knee	287	28.2	6	16.7
Bones of leg	33	29.0	3	1
Ankle	97	19.5	6	1
Bones of foot	97	19.5	6	1
Total	815	...	24	...

*In addition to the amputations reported above as performed for gunshot fracture during the war, there were 568 amputations of parts of the lower extremity, with a mortality of 25.5 per cent, and 135 of the upper, with 10 per cent, mortality on account of extensive flesh wounds, in which the fatality was due mainly to shock.

The total number of cases recorded in reports of sick and wounded was 5,825,480, with a total mortality of 166,623. The total number of gunshot wounds was 230,018, with a mortality of 32,907. (The total number killed in battle was 42,724.) The total number of deaths from disease was 157,004, the principal causes of mortality being: typhoid fever 27,056; typho-malarial fever 1,059—31,115; chronic diarrhoea, 27,558; inflammation of lungs, 14,738; consumption, 5,286; small-pox, 4,717; measles, 4,246; acute dysentery, 4,084; chronic dysentery, 3,229; remittent fever, 3,853. No doubt many of the deaths attributed to "remittent fevers" were in fact due to typhoid infection, which in this war, as in many of those which preceded it, proved to be nearly as fatal to the troops engaged as the bullets of the enemy.

No question is more important for the medical officer than that which relates to the prevention of typhoid fever and the various forms of intestinal

flux which in the past have caused such enormous losses to armies engaged in active field operations. No doubt a very large proportion of the sickness from these causes could be prevented by the simple prescription—boil all water used for drinking purposes which does not come from a source that is unquestionably pure.

But the question of the prevention of these camp diseases so destructive to armies, and especially to new levies of troops in warm climates, belongs to the Section on Military Hygiene, and I must restrict myself to topics which come strictly within the province of military medicine and surgery.

I therefore ask your attention for a short time to a subject which has been of great interest to military surgeons in the past but which, in the light of our present knowledge, should be interesting to us rather from an historical than from a therapeutic point of view. I refer to the question of traumatic infections. Hospital gangrene, erysipelas, septicemia and tetanus have no longer the terror for us that they had for our predecessors, for the etiology of these traumatic infectious diseases has been elucidated by researches made during the past fifteen years and, knowing the cause, the proper measures of prevention are apparent and are systematically applied whenever this is practicable.

That the infectious diseases mentioned result from the introduction into wounds of pathogenic bacteria is now definitely settled, and in the case of erysipelas and tetanus we know the specific characters of the parasitic invader which gives rise to these forms of wound infection. But no such demonstration has been made as regards hospital gangrene, probably because bacteriologists have had no opportunities for investigating this disease since the introduction of Koch's admirable methods of research. The writer, while in charge of the surgical wards of a large general hospital at Portsmouth Grove, R. I., in 1862, witnessed a typical epidemic of this disease which served as a lesson never to be forgotten. The two wards devoted to the treatment of surgical cases were filled with wounded men from the Army of the Potomac. A considerable proportion of the cases were simple flesh wounds, progressing favorably to a cure by granulation and cicatrization. Others were of a more serious character and were attended with profuse suppuration. The hospital was favorably located on Narragansett bay; supplies of all kinds were abundant; nurses were in sufficient number and attentive but the medical officer in charge was young and inexperienced. Under his direction the wounds were systematically cleansed and dressed with absorbent lint, etc. Nature seemed to be fully equal to the work of repair, except in those cases where a mistaken conservatism at the field hospital had left compound fractures to her unaided efforts. In such cases profuse suppuration, and septic toxemia sapped the strength of strong men. Possibly it was in such a case that the mischief commenced. Doubtless it was from one or more initial cases that the infection was carried by the sponges of willing but ignorant attendants to a considerable number of wounds which up to this time were progressing rapidly towards cicatrization. The result was a conflagration. Wounds previously healthy became inflamed, painful and angry looking, and within two or three days the cause of this change

was apparent. The area of inflammation overlying the previously healthy tissues rapidly extended and sloughs formed, sometimes as large as a man's hand and extending deeply among the muscles and along the planes of cellular tissue. Fortunately the infectious nature of the malady was quickly recognized and the measures adopted arrested its progress. It is hardly necessary to say that these measures included the removal of those not yet infected from the overcrowded surgical wards, a general cleaning up, whitewashing of walls, etc., and the necessary precautions relating to the conveyance of infection by sponges, etc. The treatment of the gangrenous wounds consisted in deep cauterization by means of nitric acid applied with a swab, the removal of necrosed tissue as soon as practicable, and the application of charcoal poultices. Goldsmith's bromin treatment had not yet been suggested. Under the treatment adopted the local extension of the disease was promptly arrested, and as soon as the sloughs had separated healthy granulations sprang up and in time repaired the mischief which had so quickly occurred.

This brief account of an epidemic of hospital gangrene witnessed by myself is intended to serve as an introduction to some remarks upon the history and etiology of this affection.

It is altogether probable that it was known to Celsus, who has described a condition of wounds not properly treated, which appears to be identical with the affection known to us as hospital gangrene. Etius, who wrote in the fifth century, refers briefly to a similar affection. Some of the ancient authors appear to have described the form of wound infection under consideration by the name of "carbuncle." Rolandus, who wrote in the twelfth century, had a chapter in his third book on wounds, entitled "De Carbunculo supervenienti vulneri." Alphonsus Terrus, who, in 1534, published one of the first treatises upon gunshot wounds, was of the opinion that all wounds of this class were poisoned by the gunpowder. He gives an account of the results of such supposed poisoning which makes it appear probable that he encountered hospital gangrene. He recommended the actual cautery as a cure for this condition, and also as a preventive. Ambrose Paré combated the idea that gunshot wounds were poisoned by gunpowder or burned by the ball, and attributed the unhealthy condition into which such wounds were sometimes observed to fall, to a "corrupted state of the atmosphere." He remarks that, owing to this cause, "Nous en sommes devenus sages par l'expérience de tant de plaies, lesquelles lors que je m'efforçais à les guérir, rendoient une telle et si grande puanteur, indice et témoignage très certain de pourriture et infection, que les assistants ne la pouvoient sentir qu'à contrecœur, et avec bien grande difficulté."

Paré's treatment of hospital gangrene consisted in the application of an ointment containing pulverized alum, verdigris, and sulphate of copper. It does not appear to have been very successful, as he reports that in many of the wounded in the battle of St. Denis the wounds fell into putrefaction and were accompanied by putrid fever and other serious accidents, and nearly all the wounded died, although their wounds may have been slight and they were supplied with everything necessary for their proper sustenance and treatment. According to Paré the

wounds made by swords, pikes and lances became affected with gangrene (les pourritures) as well as those made by firearms.

La Motte, who wrote his "Complete Treatise on Surgery" early in the seventeenth century, gives a very complete account of hospital gangrene. He says: "On prend ce mot" (gangrène), "proprement pour une disposition à la mortification qui est ce qu'on appelle vulgairement *pourriture* à l'Hôtel Dieu de Paris, laquelle survient et accompagne presque toutes les playes qui sont traitées dans cet Hôpital, et la plus grande partie des absces que l'on y ouvre, a cause de l'air corrompu qui y regne et que ces blessés y respirent."

The practice of surgery in a hospital where the opening of an abscess was likely to be followed by rapidly spreading gangrene must have been rather discouraging, and so long as the idea prevailed that this resulted from "a corrupted condition of the air," rather than from direct infection conveyed from wound to wound by instruments, sponges, etc., there was little chance of eradicating the evil.

Ponteau, who wrote in 1783, referring to the prevalence of gangrene in French hospitals, raises the question whether such institutions are not, on the whole, more pernicious than useful to mankind. What would these surgeons of two hundred years ago have thought of our laparotomies for removal of the appendix, etc.; of our operations upon the principal joints; and of the absence of "surgical fever" after serious operations made antiseptically or with aseptic precautions?

Mr. John Bell, in his "Principles of Surgery" published in 1799, says:

"There is no hospital, however airy or well regulated, where this epidemic ulcer is not found at times." (p. 112). "He must indeed be ignorant who disputes this hospital sore being a general disease of the system; he must have observed very little who does not know it to be absolutely an infection." (p. 117). "Is the surgeon to seek for washings and dressings, use ointments and plasters, and expend butts of wine to cure such a disease? No; let him bear this in mind that no dressings have ever been found to stop this ulcer—but, on the other hand, that out of the circle of the hospital the patients are safe; carry them anywhere, and at any expense, even to a stable or a dunghill." (p. 118).

No doubt this was good advice in the absence of any exact knowledge as to methods of disinfection, for even if the infectious material was destroyed in the wounds by the actual cautery, or by applications of fuming nitric acid, there was always danger of re-infection so long as the patient remained in the infected hospital wards.

The total number of cases of gangrene reported during our civil war, as occurring among the wounded of the Union armies, was 2,642. Of these, four cases occurred in 1861; 223 in 1862; 623 in 1863; 1,611 in 1864, and 135 in 1865. 1,361 cases terminated in recovery, and 1,142 were fatal; but in a considerable number of the fatal cases death was due to the original injury or to other complications—septicæmia, hemorrhage, etc.

For details with reference to the principal epidemics of hospital gangrene during the war I must refer to the interesting reports of Acting Assistant Surgeon W. W. Keene, U. S. A.; Surgeon J. H. Brinton, U. S. V.; Surgeon M. Goldsmith, U. S. V.; Assistant Surgeon William Thomson, U. S. A., and others, extracts from which will be found in the third surgical volume of the "Medical and Surgical History of the War."

The facts detailed in these reports correspond with those previously observed in various parts of the world, and show that hospital gangrene is a local disease due usually to the infection of wounds from previous cases.

This brings us to the question as to the origin of the primary cases in an epidemic, a question which is of special interest, not only as regards this disease, but in its bearing upon the etiology of other local infectious processes.

Do epidemics originate *de novo* as a result of an increased pathogenic power on the part of some common putrefactive microorganism, or is there a specific "germ" of hospital gangrene? The former supposition appears to me to be more in consonance with the facts relating to the origin of epidemics, and is sustained by extended experimental researches which show that the pathogenic potency of many bacteria is greatly intensified by cultivation in albuminous fluids and under favorable conditions. This is true of the *pus cocci*, which may thrive upon the surface of the body of healthy persons or upon mucous surfaces as harmless parasites; but which under unfavorable conditions may invade the tissues producing acute abscesses, erysipelatous inflammations or gangrenous sloughs, according to the pathogenic potency of the micrococcus and the degree of vital resisting power on the part of the tissues. The streptococcus pyogenes from a malignant case of erysipelas or from the abdominal cavity of an individual who has succumbed to puerperal peritonitis may give rise, when introduced beneath the skin of a healthy person, to the most violent local inflammation and to general septicæmia. But if cultivated for a length of time in unfavorable artificial media its pathogenic potency may be so reduced that it gives rise to a local abscess only.

The same has been demonstrated, by experiments upon the lower animals, to be true as regards certain bacteria found in putrefying material. Some of these when injected beneath the skin of a mouse, a rabbit, or a guinea pig, give rise to a rapidly fatal septicæmia; others cause an extensive inflammatory oedema in the vicinity of the point of inoculation; still others to a progressive gangrene. By inoculating from animal to animal, the virulence of the pathogenic microorganism inducing these morbid phenomena is increased, so that the smallest fraction of a drop of blood, or of bloody serum from the subcutaneous tissues of an animal recently dead from such an inoculation suffices to kill another animal of the same species within a brief period. But there is another element which influences the result when virulent putrefactive material is introduced beneath the skin of an animal for experimental purposes, or into an open wound by accident, i. e., the vital resisting power of the tissues. The body of a dead animal under favorable conditions of temperature is quickly invaded by putrefactive bacteria. But in the living animal such invasion is successfully resisted in many cases, even when putrefactive bacteria are brought in contact with open wounds. This is especially true as regards carnivorous animals, while the herbivora are especially susceptible to local or general infection when putrefactive material is brought in contact with an open wound. There is also a difference in individual susceptibility in animals of the same race. As a rule, young animals are more susceptible than adults, and susceptibility to infec-

tion is increased by depressing influences, such as insufficient food, excessive exertion, bad air from overcrowding or putrid emanations, etc.

It is under such depressing influences that epidemics of hospital gangrene have commonly had their origin. That the disease may originate independently of pre-existing cases seems to be well established by the history of independent outbreaks in distant parts of the country during the war, in new hospitals and among wounded men brought directly from the field of battle.

Billroth, in his "Surgical Letters from the War-hospitals in Weissenburg and Mannheim" (1870), says:

"While I was at Mannheim but a single case of hospital gangrene occurred. This was in barrack J of the hospital which had been placed under my direction. The medical officer of the day did not recognize the disease and first called my attention to it on the third day. Fortunately no other cases had become infected. I cauterized the wound (a gunshot fracture of the upper arm) with fuming nitric acid and after separation of the slough it was again healthy. In Darmstadt, in the great barrack hospital, two or three cases occurred which were treated the same way and isolated. So far as I am informed this was the end of the trouble."

In discussing the origin of these cases Billroth says:

"Where did the contagion come from for the one case in Mannheim and for the cases in Darmstadt? That I really cannot say, but I suspect that the infectious material was attached to lint which had been made from hospital linen, or had been scraped in a hospital in which hospital gangrene existed. This suspicion may appear very singular to many physicians, but will serve to show how thoroughly I am convinced of the specific origin of hospital gangrene."

To the writer it appears far more probable that these were cases of the *de novo* origin of gangrene as a result of the introduction into a suppurating wound of saprophytic bacteria which, owing to favoring conditions in the wound itself or to slight resisting power on the part of the tissues, had acquired sufficient pathogenic virulence to enable them to invade living tissues. It may be that there is some particular saprophyte, which is widely distributed, to which this result is commonly due; or it may be that there are a number of putrefactive bacteria which under favorable conditions may acquire this power of invading living tissues. The result is probably due, to some extent, to the development of toxic ptomaines in the secretions of the wound by putrefactive bacteria present in these secretions, which, being absorbed, lower the vital resisting power of the tissues. Deep and profusely suppurating wounds, and especially gunshot fractures of the larger bones, in which pockets and sinuses occur from which it is difficult completely to remove accumulations of pus, furnish the conditions most favorable for the development of such pathogenic virulence as may suffice to make a saprophytic bacillus a facultative parasite.

The greater liability to the development of hospital gangrene in wounds complicated by fracture of bones is shown by the accompanying table, which is taken from the "Medical and Surgical History of the War." (Third Surgical Volume, p. 824.)

It is a remarkable fact that while the larger number of cases occurred in wounds attended with fracture, the greatest mortality resulted in simple flesh wounds.

From our point of view the etiology of hospital gangrene does not differ materially from that of

traumatic erysipelas so far as general conditions are concerned, but the two diseases are doubtless due to different microorganisms. That which is the usual cause of erysipelas is now well known to bacteriologists under the name of streptococcus pyogenes, or streptococcus erysipellatus.

SUMMARY OF 2312 CASES OF GANGRENE, INDICATING THE RESULT AND RELATIVE FREQUENCY.

Seat of Injury.	Recovery.	Fatal.	Un- der- treated.	Total.	Percent of Fatality.	Percent of Recovery.
Flesh wounds of head, face, and neck	5	7	12	24	60	22.5
Fractures and penetrating wounds of head, face, and neck	32	16	48	96	37.5	37.5
Flesh wounds of trunk	35	32	75	142	47.9	29.5
Fractures and penetrating wounds of trunk	44	97	141	282	57.1	28.2
Flesh wounds of the upper extremities	47	50	102	199	51.3	30.6
Fractures of the upper extremities	456	245	701	1,399	50.9	30.6
Flesh wounds of the lower extremities	125	127	252	504	50.2	29.8
Fractures of the lower extremities	596	568	1,164	2,328	48.7	30.6
Aggregates	1,261	1,342	139	2,742	45.6	30.6

Whether hospital gangrene is a specific infection in the same sense that erysipelas is, i. e., an infection due to a specific microorganism has not been determined, but it seems probable that such is the case. It does not follow from this, however, that all cases of these traumatic infectious diseases originate by direct or indirect transfer of the infectious agent from previous cases. Erysipelas does not necessarily result from the introduction of streptococcus pyogenes into an open wound. This streptococcus is frequently found in the pus of acute abscesses unattended with any erysipellatous inflammation. But under favorable conditions it may develop virulent properties, which are manifested especially by a tendency to invade the tissues by way of the lymph channels and along cellular planes, producing a dilation of the capillary vessels and more or less serous effusion, leading often to suppurating and sometimes to necrosis of the invaded tissues. The development of first cases of either disease probably depends upon predisposing causes relating to the individual or his environment. A traumatism is more likely to be followed by erysipelas in a man whose vitality is below par on account of intemperance, insufficient food, bad hygienic surroundings, etc., and the same is true as regards hospital gangrene. Under such conditions the comparatively harmless streptococcus pyogenes may overcome the barriers established by nature to resist invasion by saprophytic bacteria, and having acquired the power to multiply as a parasite in tissues enfeebled by the causes mentioned it soon attains a pathogenic virulence which enables it to invade healthy tissues when transferred by accidental inoculation to another individual.

The view here advanced with reference to the *de novo* origin of erysipelas is supported by the fact that solitary cases frequently occur at remote military posts. Thus during the past year twenty-eight cases are reported as having occurred among the enlisted men of the United States army. Of these eighteen occurred at eighteen different posts, while three posts had two cases each and one post had four.

The facts relating to the etiology of pneumonia correspond with those referred to as relating to

that of erysipelas. In this disease, also, the specific cause has been shown to be a micrococcus (*Mic. pneumoniae crouposa*) which is frequently found in the salivary secretions of healthy persons, and which varies greatly as to its pathogenic virulence. Solitary cases of the disease occur at our military posts, as elsewhere, as a result, no doubt, of predisposing and exciting causes which give the specific cause the mastery over the resources provided by nature for resisting the local infection which constitutes the disease in question.

The total number of cases of traumatic erysipelas reported as occurring in the armies of the United States during the war was 1,097, with a mortality of 41 per cent.

The micrococcus which is now recognized as the usual cause of erysipelatosus inflammations is capable of growing either in the presence or absence of oxygen: i. e., it is an aerobic and facultative anaerobic microorganism. We infer that the same is true as regards the microorganism which produces hospital gangrene. But in the case of tetanus, which has been proved by recent researches to be an infectious malady due to a bacillus widely distributed in the superficial layers of the soil, it has been shown that this bacillus is a strict anaerobic. It does not grow in the presence of oxygen and could not thrive in superficial wounds. This probably accounts for the fact that epidemics of tetanus are not common. The cases which occur are for the most part sporadic cases, due in each instance to infection, resulting from the introduction of surface soil or dust containing the tetanus bacillus. Such material in an open wound might be innocuous. But introduced into the depths of a gunshot wound, into a closed amputation wound, or into a punctured wound made by a rusty nail, for example, the tetanus bacilli (spores) present find the conditions favorable for development and this fatal infectious malady results.

Sporadic cases of hospital gangrene probably occur in a similar way, but as there is a free escape of virulent material from the infected wound, the danger of the disease being transmitted to other wounded individuals is infinitely greater.

The total number of cases of tetanus reported in the "Medical and Surgical History of the War" is 505, or a little more than two per thousand of the total number of injuries by weapons of war. More than one-fourth of the cases followed operations upon the extremities; 116 after amputations, and fifteen after excisions. We can scarcely doubt that a majority, at least, of these cases would have been prevented by modern methods of treatment—antiseptic or aseptic.

The same statement applies to the considerable number of cases reported under the heading pyemia. It seems probable that of the 2,818 cases reported under this heading a large proportion were in fact cases of septicemia resulting from wound infection. The very great mortality, and the results of post-mortem examinations made, indicate this; but as it was before the days of bacteriological research there is no direct evidence on record showing the presence of bacteria in the blood and in the metastatic abscesses found in the lungs, the liver, the kidneys, spleen or joints in those cases in which an autopsy was made. Doubtless septic toxemia occurred in numerous cases but, as stated, we infer that a majority of the cases reported under the heading

pyemia were in fact cases of septicemia resulting from infection through the wound, by the pathogenic micrococci which are commonly concerned in this form of "blood poisoning," and especially by *staphylococcus aureus*. The mortality in the class of cases under consideration exceeded 97 per cent. Out of the total number of deaths (2,747) but twenty-one are reported to have resulted from other complications,—viz., hemorrhage seven, gangrene six, tetanus two, erysipelas one, peritonitis one, and typhoid pneumonia four.

One of the questions to be settled by the military surgeon in the next great war, which we earnestly hope will not occur on this continent, is to what extent the large mortality which has heretofore occurred from traumatic infections can be prevented by antiseptic methods of treatment. Certainly there will be no excuse for the occurrence of septicemia after amputations, or for the appearance of erysipelas or hospital gangrene in wounds made by the knife of the surgeon. But how far it may be practicable to prevent such complications in gunshot fractures remains to be seen, and the proper treatment of such injuries is an important point for consideration. If such cases could at once receive skillful surgical treatment, including the removal of splinters, foreign substances carried into the wound by the bullet, and antiseptic dressings, no doubt many would be saved without loss of life or limb. But the changing fortunes of the battlefield often make it impossible for medical officers to give such prompt attention to the wounded. It is generally conceded that on the firing line nothing more should be attempted than the arrest of hemorrhage, and such support to the fractured limb as will enable the wounded man to bear transportation to the field hospital with the least possible suffering. It is here that the fate of the unfortunate victim of war will often be decided, and the responsibility resting upon the military surgeon under such circumstances cannot be overestimated. His decision with reference to operative interference must be prompt, and will often be governed by circumstances other than those laid down in surgical textbooks. How far must the man be transported before he will reach a resting place at a permanent hospital? What are the means of transportation? Is he to be left at the mercy of the enemy as a prisoner of war? Shall his case be passed by because of others more urgently requiring attention? Many a leg must be sacrificed which might be saved under more favorable conditions, and conservative surgery must often yield before the inexorable contingencies of the battlefield.

In future wars the question will be decided as to the propriety of performing laparotomy at the field hospital in penetrating wounds of the abdomen, for the purpose of exploration, and suturing the intestine if it is found to be wounded. This is so important a question that I have attempted to make it the most prominent surgical topic for discussion at the present meeting, and trust that as a result of this discussion we may arrive at definite conclusions as to what our action should be if called upon to treat such cases.

What has been said will suffice to indicate to the young medical officer that much is expected of him; and that in view of recent additions to our knowledge relating to the etiology of the more common camp diseases, and of traumatic infections, and to our resources for preventing and curing such dis-

cases, we have a right to expect a great reduction in the mortality from sickness and wounds in the armies engaged in future wars.

MEDICAL EDUCATION IN THE UNITED STATES.

An Address delivered before the Section on Pedagogy of the Pan American Medical Congress.

BY J. COLLINS WARREN M.D.

Professor of Surgery in Harvard University. President of the Section

GENTLEMEN:—The work of this Section is of a character which does not usually form a prominent part in the proceedings of medical gatherings.

In almost any department of education, pedagogy or the science of teaching is a recognized specialty.

The rapid progress which has been made in medical education in this country within the last few years has brought about such profound changes in methods of instruction, and the strides which medical science is making all over the civilized globe are bringing into view so many new fields of work, that the teachers of to-day have a far more complex and difficult task than was presented to their predecessors. The art of teaching medicine has not been taught, in this country at least; the time has arrived to take up the subject.

In introducing such a subject as this, it seems appropriate to take a brief retrospective glance at the history of medical education in this country.

There lies before me as I write, a quaint little volume entitled, "A Discourse upon the Institutions of Medical Schools in America," published in 1765. It bears the following inscription:

"To Doctor John Warren, Physician in Boston. This Copy is presented by his respectful and affectionate Friend, John Morgan, Philad'a, Feb. 27, 1783." This book may be safely regarded as the first contribution to the subject which we are to discuss to-day and the two dates are memorable; the former indicating the foundation of the medical department of the University of Pennsylvania, and the latter the birth of the medical department of Harvard University.

Dr. Morgan justly remarks that "medicine is a science as important in its object as it is difficult in the acquisition. It is very extensive in its researches and presupposes the knowledge of many other sciences. The cultivation of it requires no small abilities, and demands of those who engage in the arduous pursuit an enlarged and benevolent mind."

It is interesting to note that one whom we might justly look upon as the father of medical education in this country and who "had spent five years in Europe under the most celebrated master in every branch of medicine," should have taken so optimistic a view of the knowledge of medicine at that time as to say: "The industry of many centuries has already been employed to bring Physic to that degree of perfection at which it is now arrived." Fortunately he adds: "It will still require a long time to remove the obscurities which yet veil many parts of it."

Three years after this book was written, Pennsylvania held her first medical commencement and the provost justly remarked: "This may be considered the birthday of medical honors in America."

The men who started this movement had received much encouragement from across the ocean and the

remark of one of their teachers, Dr. John Fothergill of London, is of special interest to those concerned in the work of this congress. Writing to James Pemberton in 1762 he recommends Drs. Shippen and Morgan as men well qualified for the work of teachers, "both of whom," he says, "will not only be useful to the province in their employment but if suitably countenanced by the legislature will be able to erect a school of physic among you that may draw students from various parts of America and the West Indies."

During the colonial period of our history it was the custom for young men who entered upon the study of medicine to become regularly apprenticed to some practitioner for a term of three or four years during which time the preceptor was entitled to the students' services in preparing and dispensing medicine, and serving as an assistant in minor surgical operations. As a return for this, the physician was obliged to give the student detailed and thorough instruction in all the branches of medicine. Many of the leading men frequently had several students in their office, constituting a small class, who were drilled as regularly in their studies as they would be in college. In some instances the term of apprenticeship was extended even to six or seven years.

When the medical school sprang into existence it was at first intended merely to supplement the apprentice system, and as means of communication of one part of the country with another were exceedingly limited it was found desirable to concentrate school work into as small a part of the year as possible. Hence the origin of the short term of four months which has clung so persistently to the American system.

I will not undertake to weary you with a detailed account of the history of the development of our system of education. Suffice it to say that the close of the century found schools established not only in Pennsylvania and Massachusetts but in New York, Maryland and Vermont. There were, however, in 1810 only five medical schools in existence with an aggregate number of medical students of about 650, of whom 100 received the degree either of bachelor or doctor of medicine. The bachelor's degree was given to those who had attended one full course of college instruction. It was hoped that such students after a short period of practice would eventually return to take the higher degree, but as this expectation was not fulfilled the degree of bachelor of medicine was soon wisely abolished.

A noticeable feature of the education of that early period in our medical history were the requirements for a high standard of general education. Those students who did not possess a college degree were expected to pass an examination in Latin, mathematics and "Natural and Experimental Philosophy."

To obtain the degree of doctor of medicine it was necessary that the applicant should have been a bachelor of medicine for at least three years, should have attained the age of twenty-four years and should write and defend a thesis publicly in the college.

When we consider how imperfect was the knowledge of chemistry, physiology and even anatomy, and many other branches of medical science, and how

¹ N. S. Davis, Med. Ed. and Med. Institutions in the United States of America, 1877.

² William Pepper, Higher Medical Education, 1877.

little of what we now consider the foundation of medical education there was to teach—such a course cannot be regarded as a very complete and exacting one.

"Under these influences the first thirty years sufficed to cause the bachelor's degree to be abandoned by all the schools, the number of professors in each school to be double, and the length of the annual college term to be shortened one-third." (Davis.)

Such was the standard of education with which the present century opened. New schools continued to be created, not infrequently in connection with some university, as in 1810 at Yale University, in 1817 in Lexington, Ky., in 1820 at Brunswick, Me., in 1825 at Charlottesville, Virginia, until in 1840 twenty-six new medical colleges had been added to the list, the whole number of students in the country amounting to 2,500, the population in that year being 17,069,453.

A glance at the report of a committee to the Medical Society of the State of New York in 1833, gives a good idea of the amount of work done by the schools at that period.

In the twenty schools mentioned in this report the number of courses of lectures required was two, with one exception—that of the University of Virginia, where three courses were required; and to the credit of this university be it said, the length of each course was ten months, whereas, the almost invariable custom of the other schools was to give a course of four months' duration only. The time of study purported, however, to be in all cases three years, "including the time devoted to lectures," as is stated in most of the reports. This straw indicates that at that time the chief dependence, or nearly so, was placed upon the extra-mural instruction which was given to the student. At Yale University there was this additional requirement, namely, that the student was required to study four years, "if he had not graduated," which phrase, I presume, means if he had not already taken the academic degree. This seems to be the first intimation that a longer term than the standard then set was necessary for a complete equipment for the practice of medicine.

The Medical Institution of the State of Georgia (incorporated in 1828) gave at first the bachelor's degree with one year of study, but immediately abandoned it for the usual curriculum.

In the University of Pennsylvania, to which we look for the standard in these early, as well as later days, two full courses were required, but as in many other schools one course only was demanded from those who had attended a course at some other reputable school. In addition, a course of clinical instruction in one of the Philadelphia hospitals was required.

The course was then three years in length, but as each course of lectures lasted only four months, it was expected that during the remaining portion of the first two years the student should receive private instruction.

As the period of the school term was so short, it is interesting to note at what time of the year the various courses of lectures began.

This, it will be seen, varied greatly according to the geographical position of the institution. At Dartmouth and the University of Vermont the term began in August. In Bowdoin College, Maine, however, it began in the middle of July, continuing until

the middle of May—that is, the term time in the far north was in the summer or spring.

At Yale and Harvard and in Philadelphia and New York the term opened at the end of October or the beginning of November, as did also the schools in North Carolina and Kentucky. The University of Virginia, with its long course of ten months, began September 10.

Although the term time was exceedingly short in some schools a large amount of work was crowded into the daily routine of the students. Five or six systematic lectures a day, with attendance on clinics and dissections when possible, was considered nothing more than a fair amount of work for the medical student to digest properly.

This system of teaching remained practically unaltered in 1851, if we may judge from a report to the Committee on Medical Education of the American Medical Association.² In regard to the private instruction which was supposed to continue during the remaining eight months of the year, the report states that a very large proportion of students simply read medicine under the direction of their preceptors. Anything like careful instruction upon the part of the teachers did not exist. The student neither while attending lectures nor while in his preceptor's office was encouraged in anything like faithful and rigid study. To remedy the defect, private schools for teaching medicine were founded by enterprising physicians and surgeons and these quiz classes which were then inaugurated, became a prominent feature of the national system of teaching. Many a distinguished professor has first won his spurs at these private schools, and many valuable experiments in medical education were carried on by these men. As the college term has lengthened, the necessity for these accessory courses has diminished, and in many cities the extra-mural instruction, whether by private school or by teacher, has passed into history. No one will, I presume, regret the departure of the year of private teaching, "by some respectable practitioner," whose certificate, purchased by a handsome fee, came eventually to have so little meaning. When this custom was first inaugurated it was the sole method of inspection, and during the long period of apprenticeship the student received a large amount of instruction of the most valuable sort. When the medical school came into existence the attempt was made to combine the two systems. The practitioner, relieved from the responsibilities of giving a complete course of study to the student, gradually relaxed his efforts as a teacher until this part of his daily work came to have only a nominal value.

According to Davis it consisted in 1877 in little more than the registry of the student's name in the doctor's office, permission to read the books of his library or not, as he chose, and the giving of a certificate of time of study for the student to take to the medical college where he expected to graduate.

At the beginning of this century the successful practitioner gave a prominent place in his household to the medical student. I have often heard my father and many other practitioners of his day tell stories of the school life of those times. The office in the old homestead where I began the practice of medicine, then a luxurious library, was in those times a plain room with a sanded floor, occupied during the day by a small band of medical students who all

²W. Hocker, M.D. 1851.

boarded in the same house. The old room was the scene of many amusing stories of schoolboy life, and also of thrilling tales of escape from the indignant pursuer, by the hero of some graveyard scrape which was rendered necessary by the peculiar laws of that period. This phase of student life has long since passed away and the equally agreeable and far more profitable experience of hospital life has taken its place. Would that I could add that such hospital experience was now the privilege of every medical student in the land.

As we approach the middle of the century, we find the nation growing rapidly in population and prosperity, and a corresponding increase in the numbers and activity of the medical profession. From 1830 to 1845 the number of medical schools in the United States had more than doubled.

At a meeting of the Medical Society of the State of New York in 1839, when the subject of medical education was brought forward, it was proposed to hold a national medical convention the following year in Philadelphia, consisting of representatives from the different schools and State societies. No response was made to the action of this society, but in 1844 Dr. N. S. Davis, then a delegate from Broome county, New York, offered a resolution that a national convention be called in 1846, and the American Medical Association thus sprang into existence, the fundamental idea, which brought about the formation of the association, being the improvement of our system of medical education.

It was high time that some such movement should take place, as the rapid increase of the number of medical schools brought with it a constant increase in the laxity of methods of teaching.

The equipment of a new school was sometimes pathetic in its meagerness—a mannikin and a few lecture rooms constituting the entire "plant" of the infant institution. It would not do to question the dean too curiously about the clinical facilities which the school enjoyed; and as for laboratory work there were few teachers sufficiently advanced in their ideas to think of criticising the absence of such instruction. There was, indeed, no time for it. Every available space in the tabular view was filled with lecture hours. Professors were asked to come from neighboring towns to assist in teaching, and often gave two lectures in the same day. This cramming process, which seems so peculiarly American in its hustling activity, is perpetuated to the present day in a limited number of schools, chiefly those situated far from medical centers. As Oliver Wendell Holmes has said, life at that time was cheap; medical visits in the country were worth only twenty-five cents apiece, and the ambitious student could not afford to make an expensive outlay for his future work.

The American Medical Association therefore justly put on record its opinion, "that the abuses which exist in the modes of medical education pursued in this country demand the serious consideration of the profession," and at each meeting it continued to sound a note of warning on this all-important subject.

One of the principal reforms which it proposed to bring about was the lengthening of the term of each year from four to six months, and you will doubtless be somewhat surprised to hear that at the second meeting of the Association, which was held in Boston, a paper was presented from the faculty of Harvard University opposing this proposition.

Tempora mutantur et nos mutamur in illis.

If Harvard was unwilling to lead in the matter of reform at that time, it is not surprising that the other schools should not have been persuaded to change their customs. To the Chicago Medical College—which was founded in 1859—must be given the credit of having been the first to attempt to lengthen the college course and to establish the system of teaching upon the so-called graded plan.* The school was in fact organized for this express purpose.

Little change was, however, effected by the Association in the methods of teaching at that time, although the discussions which were constantly held were destined eventually to bring forth good fruit. During the following decade little was done in the way of reform.

Graduating from the academic department of Harvard in 1863, I had an opportunity to study personally the methods in vogue at that time and am the more competent to express an opinion as I passed one year of my course of study in Philadelphia. The old system of medical education was then in all its glory and presented a striking contrast to one who had been subjected for four years to the strict discipline of a well conducted university.

The course of lectures in Philadelphia began about the first of November, and the day was occupied in a bewildering succession of lectures, on all of which the student felt called upon to attend, as he had been obliged to "take out tickets" for the full course. The teachers were able, conscientious, and in many cases brilliant men, and many a lesson then learned has been of value in after life. Clinical teaching was, however, largely crowded aside by the superabundance of systematic lectures. The course came to an end on the first of March, and the class—which was an enormous one—was allowed to scatter to the four quarters of the country. Many of my classmates returned the following autumn, and after attendance on a second course of lectures and having also handed in the certificate of study from the "respectable practitioner" were able to graduate in the following March; that is, after having been connected with the school less than eighteen months. This may appear to the younger members of this Section an absurdly short curriculum, but there were a considerable number of enterprising young men who did not propose to occupy so long a time in obtaining their education.

You will remember what has already been said about the period of the year occupied by the school term. At that time there were not only schools who had their college "year" in the winter, but there were spring "years" and summer "years" as well.

Several of my friends proposed accordingly, after leaving Philadelphia in March to take a spring "year" at another school, in accordance with a custom which many at that time followed. Such a student was therefore able on July 1st to show to the examining body, tickets for two full courses of lectures and a letter testifying to private instruction. It was notorious that many students at that time were able to obtain a degree after nine months only of medical study. The custom of short courses of study at different periods of the year unfortunately still prevails. This zodiacal paradox has not yet been fully eliminated from the medical calendar. The condi-

* N. S. Davis. Contributions to the History of Med. Ed., etc., 1877.

tion of teaching at Harvard was practically the same as at Philadelphia.

It is not surprising that the best class of students were dissatisfied with the opportunities, and that the number of those who found it necessary to go to Europe to complete their education was constantly increasing. Two and even three years of study was not considered too long a time to occupy in this manner. It is true that spring terms of a supplementary nature were organized by most schools, and those students who chose to remain could receive instruction throughout the year. The majority of students, however, disappeared, many of them employing their time in other occupations to earn sufficient money to pay for a second course of lectures. The class of individuals who studied medicine at that time seemed far inferior to the medical student of to-day in culture and refinement. President Eliot says of the medical students of that period: "In this university, until the reformation of the school in 1870-71, the medical students were noticeably inferior in bearing, manners and discipline to the students of the other departments; they are now (1888) indistinguishable from other students."

The date which I have just mentioned marks the era of a great change in the history of medical education. The rising generation of teachers were not content with the antiquated methods of a previous century; they had learned of a new order of things in the centers of medical learning in Europe. As the old generation of teachers went out and a new one came in, the modern ways of teaching grew into a substantial system which had come to stay. Harvard adopted the graded course of three years' study, but she did also far more than that—and in this respect she stands in advance of almost every other school in the country—she lengthened her course to nine months, so that her two terms correspond with those of the other departments of the university and represent a full year's work.

I will not undertake to record the history of the reform in medical education since that time; it is familiar to most of you. The example which has been set to the rest of the country by the University of Pennsylvania and by the College of Physicians and Surgeons of New York is too well known for me to repeat them here.

While criticising, as I have done, the work of a previous generation, I ought to remind you that our forefathers accomplished what they did only by individual efforts. There were no governments, and as a rule no liberal benefactors to back them in their undertakings. Their schools had to be conducted on business principles, with a keen eye to the practical success of their venture. During the past twenty years, it is true, a number of State universities have been established. In the University of Michigan, and possibly in one or two other State universities, the medical professorships like those of other departments, are sustained by the income from the general endowment, independent of fees derived from medical students; but, as a rule, the success of the school has depended upon the patronage which it has received. It may be justly said, therefore, that the whole system of medical education in this country is the spontaneous outgrowth of the work of the medical profession, and that it is due to their public spirit and disinterestedness that so important a department in the educational devel-

opment of a great nation has been brought to its present state of excellence.

The good work has, however, but just begun. The reform of medical education is still in its infancy. If we are to believe all the glowing announcements which we read in the annual catalogues of the various schools, we might be lulled into a sense of calm security for the future; but, unfortunately, the actual practice of many. I might say a majority, of the schools does not come up to the ideals which are here set forth.

The essential points in the new scheme of education have been well stated by our President, Dr. Pepper:

1. The establishment of a preparatory examination.
2. The lengthening of the period of study to at least three full years.
3. The careful grading of courses.
4. The introduction of ample clinical and laboratory instruction.
5. The establishment of fixed salaries for the teachers.

In a general way we may obtain some notion of the improvement which has been made by a study of the report of the Illinois State Board of Health for 1891. According to this report there are now 148 medical schools of all kinds in the United States and Canada. The number of those requiring certain educational qualifications for matriculation is 129.

The number of schools requiring attendance on three or more courses of lectures was, in 1882, twenty-two. In 1891 the number was eighty-five.

There has been also a gradual increase in the duration of the lecture terms from an average of 23.5 weeks in 1882-83 to 26.3 weeks in 1890-91. In 1882-83 there were eight colleges that had but sixteen weeks; the number of colleges having terms of six months or more is now 111. The number of colleges which have graduated students at the end of the second course of lectures the present year is less than 10 per cent. of the whole number of schools in the country.

There are now in the United States thirty-two examining and licensing bodies that do not give instruction. Although the work of these licensing boards is far from uniform, a great deal has been accomplished by them. There are at the present time fifteen States with Practice acts that require an examination of all persons desiring to practice medicine in the respective commonwealths. These States include nearly 50 per cent. of the entire population. In many States the whole complexion of the medical practice has been changed by the clarifying influences of these bodies. The reports on medical education by the Illinois board, I do not hesitate to say, have exerted a more powerful influence on the movement in education than any other publication which our medical literature has produced.

The effects of these Medical Practice acts which establish a minimum of time spent at medical lectures and provide an examination for those who wish to become practitioners, are shown in the statistics which have just been given. At the present time State examinations are required in Minnesota, North Dakota, Montana, Washington, North Carolina, Alabama, Florida, Virginia, New Jersey, New York, Nebraska, Maryland and Utah.*

* Introductory Address, Philadelphia, 1877.

* Millard, "The Necessity and Best Methods of Regulating the Practice of Medicine," *Journal Amer. Med. Ass'n*, July 30, 1892.

Millard, who has had experience in framing the act of Minnesota, believes that it would be an improvement upon the Medical Practice acts at present in existence, to separate the two functions of the board, the licensing power and the educational supervision. He thinks that the best interests of the public will be observed by assigning the duties of the State licensing power to the various State Boards of Health. The regulation of all forms of education should, on the other hand, be vested in a central power consisting of a single board, to be known as a State Bureau of Education, with power to regulate all educational institutions granting degrees, together with the power of granting charters and revoking the same; particularly should this apply to all institutions wishing to afford the community any of the various forms of higher or special education.

Having thus sketched the progress of medical education up to the present time, let us now glance at some features of the present system in which it is desirable that further improvement should be made.

The importance of a preliminary training for the study of medicine is a problem which has occupied the attention of our most prominent teachers. That the medical student should have received a fair amount of education goes without saying. The importance of a proper preliminary education is thus forcibly stated by that most experienced of German teachers, Professor Billroth. He says in reply to the objection to a preliminary study of the natural sciences as a basis of a medical education:

"The educated of all nations should not fail to encourage to their utmost knowledge and study—in all countries and stations of life they should not fail to maintain the standard which they have set up, both for themselves and others; they should not fail to support the government in all efforts directed towards this end.

"The physician, the lawyer, the school teacher and the clergyman form the nucleus of culture in the community; they are, especially in the country or small towns, the representatives of the educated element of society. The people seek their advice in time of need, and they are their sole source of knowledge in many things.

"To neglect the education of such persons, to lower their mental and scientific standard, to bring them up so that they know no better education than the tradesman, the tailor and the cobbler, would be, in my opinion, the suppression of the educational development of a nation and is a policy both corruptible and immoral in principle, as it would inevitably ruin a nation and bring it prematurely to that point of decadence where it would become the prey of others."

The importance of these views is fully appreciated in Germany, where the professional schools are integral parts of the university, and entrance to the professional schools depends upon the previous completion of the course in philosophy, a course which corresponds to that of our academic degree.

In Dr. Holmes' suggestive article¹ on this subject it is shown that while the increase in the total number of medical students has been very great during the last decade, the increase in the number of "college men" who have entered the profession has been very slight, and in some of the more prominent schools the percentage has even slightly diminished. The author says: "It can not then be doubted that relatively a smaller number of medical students have a bachelor's degree than in 1880, though the education of the average medical student is superior to the average medical student ten years ago." Al-

though the proportion of medical students to students of law and divinity is greater in the United States, the relative proportion is as diminishing as in the last ten years, whereas in Germany, in the same period, a period during which medicine has become more of a science and the demand for surgery has increased under antiseptic methods, the proportion of medical students to the students of other professions has greatly increased. The reason for this variation in the proportion of students in the two countries is explained by the imperfection of our system of education. Educators have not had proper control and medicine has not been placed upon that dignified scientific basis which it enjoys in Germany. Dr. Holmes complains that the medical department is neglected by every university in the United States. "It is farmed out or left to shift for itself."

Harvard has recently made an attempt to overcome the difficulty by a modification of the academic course. As Welch points out in an article on this subject: "If a young man choose the medical profession he should devote at least four years to medical studies, including the preliminary sciences. If he supplements this with a year in a hospital and a year or two in study abroad, and all this work has been preceded by a college academic course, he would not be able to enter upon the practice of his profession much before the age of thirty."

Dr. H. P. Bowditch, dean of the Medical Faculty of Harvard, has strongly advocated a change which would overcome this difficulty. The average age of students who enter the Harvard academic department, as President Eliot has shown, has been gradually rising during the whole of this century until it has reached nearly nineteen years. The student who enters the medical school therefore finds himself just beginning the preparation of the real work of his life at an age when many of his contemporaries are already engaged in the productive work of their professions. In Germany the best class of students begin their professional studies at a little earlier age than that at which our young men enter Harvard College. As the course of study leading to the degree of doctor of medicine lasts five years, it follows that the German physician is ready to begin practice before he is 23½ years old.

The average age of matriculants at Oxford is 19 years, and it is perfectly possible for an Oxford student desiring to study medicine to begin his purely professional studies before the end of his second year of college life. The dean writes me upon this subject as follows:

"There are many students in our school who have had one or two years of college life either as special or regular students, and these have entered the medical school because they have felt the necessity of getting started in their life work. These men would have been glad to take the A.B. degree if it could have been procured in a shorter time, but they consider it too dearly purchased when it involves so much delay in beginning their professional life."

It seemed, therefore, reasonable to the medical faculty of Harvard to make the following proposition, namely, that the academic council should consider the expediency of granting the degree of A.B. to all undergraduates who should subsequently take the longest course of study offered at the professional school after three years' attendance in the academic

¹The Forthcoming Report of the Bureau of Education on Professional Education in the United States," Jour. Amer. Med. Assn., Vol. 1, No. 14, 1893.

²Some of the features of the Medical School of Harvard University, 1888.

³Remarks made at a meeting of the American Medical Association.

department—the professional degree and that of A.B. to be given simultaneously at the end of the professional course. One of the medical studies at least can be obtained in the usual college curriculum, and general chemistry is frequently “anticipated” by students who enter the medical school. It is hoped, indeed, that this course will soon become one of the “preliminary studies” to medicine. It would be a short step to place one or two more of the scientific medical studies on the list of academic electives, and a whole year could be thus anticipated. The relations of professional schools to the university are not appreciated in the same light that they are in Germany, and the proposition of the medical faculty after much discussion was finally declined. The advantages of a more intimate relation between the medical school and the university are clearly set forth by Welch in the article referred to. The duplication of laboratories is thus avoided, and men of different branches of sciences are brought more intimately together. The important departments of botany, zoölogy, and comparative anatomy cannot fail to have an elevating influence upon the work done in a medical school. How much more rapidly might not original investigation progress when different branches of science work in a common cause. It is here that the great strength of German science and progress takes its origin.

A movement in the same direction is the establishment in our colleges and scientific schools of courses of tuition, intended specially for the benefit of those who intend ultimately to study medicine. Such a course has been planned by Prof. Shaler in the Scientific School of Harvard, and a similar course is offered by the Institute of Technology.

Professor Shaler's course preparatory to medicine consists of two years. In the first year we find physics, zoölogy, botany, general chemistry, rhetoric and elementary French or German, and freehand drawing among the studies required.

In the second year there is botany, zoölogy, comparative anatomy, geology, comparative osteology, physics, qualitative analysis and themes.

It is certainly to be hoped that the medical teachers of the United States will not remain content with the very elementary examinations which are now demanded for those students who have not received a college education.

The advantage of a previous college training is shown in some statistics given by Billings¹⁰ of examinations conducted by the examining boards of the army and navy. Of those candidates who had a college degree 31 per cent. were successful, and of those who had no such degree 28.9 per cent. succeeded. It is interesting in this connection to note that taking the medical schools of Harvard, Yale, the College of Physicians and Bellevue Hospital of New York, the University of Pennsylvania, and the University of Virginia together, 46.1 per cent. succeeded, while for all the rest of the schools in a body 22.3 per cent. succeeded.

One of the most prominent features of the new education is the character and amount of laboratory work which is now required by our medical school. The new building of the Harvard Medical School, erected twelve years ago, showed the importance which its faculty attached to this means of teaching the student. Already the large addition of the Sears

laboratory has more than doubled the facilities of this department of the school. The University of Pennsylvania has felt the necessity of increasing the facilities of laboratory work and has received a munificent endowment for its department of hygiene. The literature of this part of our educational system is already becoming voluminous. The recent reports of Vaughan and Holmes in behalf of the work done at the University of Michigan and of the College of Physicians and Surgeons of Chicago, respectively, show the interest which is taken in this subject in some of the western schools.

General chemistry forms so large a part of the first year's work in the Harvard Medical School that it is proposed to make room for other valuable work by making this study one of the requirements of admission. This course is already anticipated by most of the college graduates. The course on embryology and histology is at present a required one, and lasts throughout the year. Students are obliged to keep books in which drawings are made of the specimens studied and these books are examined by the teacher. Those who do not possess microscopes are provided with them by the school, and the equipment of this department enables it to handle classes of 150 students. Prof. Minot, who conducts this course, urges the addition of a course on biology to the work of the first year, as it would not only enable the student to pursue many of his studies more intelligently, but would add greatly to the value of all original work done by the student or physician.

The new four years' course has been so arranged that the technique of bacteriology comes in the first year. This is a time when the student has more time for laboratory work, and it paves the way for special work in the study of these organisms in connection with pathology, which is placed in the second year. I shall leave a more detailed statement to Prof. Ernst, who will have something to say upon this subject later. Bacteriology needs no special plea to-day. It cannot even be regarded as a purely scientific study. No practitioner of medicine or surgery who emerges from one of our schools to-day should be considered properly equipped for his work unless he has been trained in such a laboratory. No physician can expect to unravel the secrets of disease without a practical knowledge of the demonstration of certain forms of bacteria, and there is certainly no better school for aseptic surgery than the bacteriological laboratory.

The study of pathology at the Harvard Medical School¹¹ is conducted by Professor Councilman, not only by lectures, but by demonstrations, recitations and exercises in pathological histology. The latter course, which has hitherto been optional, is now obligatory. The relation of bacteria to disease is taught by the study of certain types of disease, as tuberculosis, suppuration, pneumonia, etc.

Demonstrations are given twice a week of material obtained from the hospitals and private practitioners. This is a laboratory exercise. Individual members of the class are called upon to study the specimens. They then carry them around to the other members of the class and demonstrate and explain to them the lesions. Each student in this way has the specimen demonstrated to him. In the course on pathological histology the student is required to make drawings of the sections studied.

An opportunity is given to a certain number of men, who have gone through with their course in pathology to act as demonstrators the following year and to assist in teaching. Places are assigned in the pathological laboratory to a certain number of students who have done well in their studies, and opportunity is given them for special study or original investigation.

A type of laboratory course, which I think is peculiar to Harvard, is that on the application of bandages and surgical apparatus. It is a purely laboratory course, is given to students at the beginning of their second year and is confined to a detailed study and drill in the practical part of such work. Bandaging is taught upon the living subject and upon wooden models. The feature of this course which is perhaps most valuable is the preparation and application of all the forms of stiff bandages. In this way every member of the class learns thoroughly the elementary part of this work before he begins to practice upon patients in the hospital, and no student leaves the school without becoming an adept in the application of the stiff bandage.

Another subject which is receiving more and more attention yearly is that of clinical instruction. The weakness of this feature of medical education was one of the glaring faults of the old system, and arose out of the fact that hospitals were far less numerous than they are at the present time, and that, from the necessities of the situation, the independent origin of the medical school became a custom which has continued almost unimpaired to the present day.

In Boston the medical school flourished for nearly one-third of a century before its teachers realized the importance of this problem. A circular was then issued in 1810, in which the statement was made that "a hospital was an institution absolutely essential to a medical school." Would that all teachers of that time had realized sufficiently that fact and had educated the public to recognize the necessity of such a close relation of the two. Many of the older members of this congress can remember the old-fashioned prejudice which resented the intrusion of students into the hospital wards. The theory of the trustee of that time was: This money was given for the cure of patients and not for the education of physicians. They could not be persuaded that the two interests were identical.

The change of feeling in more enlightened times was indicated by the benefactor of the great Johns Hopkins hospital. At the opening of that hospital in 1889 Dr. Billings showed the advantage of such a union in the following words:

"It is well known to those familiar with the subject that the sick in a hospital where medical instruction is given receive more constant, careful and thoughtful attention than do those in a hospital where no such instruction is given. The clinical teacher must do his best; keen eyes will note every error in diagnosis, every failure in results of treatment. Moreover, the very act of teaching clarifies and crystallizes his own knowledge in attempting to explain, the dark places become prominent and demand investigation, and hence it is that those cases which are lectured on receive the best treatment. I need say nothing here on the other side of the question; the value of properly trained physicians to the community and the necessity for hospital instruction in such training. Johns Hopkins understood all this, and especially directed that 'in all your arrangements in relation to this hospital you will bear constantly in view that it is my wish and purpose that the institution shall ultimately form a part of the medical school of the University.'"

The reaction in favor of clinical teaching is becoming daily stronger, and no school can hope to compete with the great schools of the country which does not have control of what is usually called "clinical facilities." This term must unfortunately still be used; for the number of schools which have a hospital of their own is yet exceedingly small. The union between the two is in most of our large cities becoming a more and more intimate one.

Another immense advantage which the possession of a hospital gives to a faculty is the control of appointments. Most schools are now obliged to select their teachers from members of the staffs of hospitals in their city who have services at times of the year which enable them to teach. These individuals are appointed by laymen who have no knowledge of or regard for the necessities of medical education. Faculties thus placed are unable to select teachers of national reputation, as there is no appointing power which enables them to give such a person the material with which to teach. This is a grave defect in our system, and one which the leaders in medical education should not forget to impress upon the profession and the public.

But, while applauding the movement in favor of clinical teaching it is perhaps well at the present time to consider whether systematic or, as it is usually inaccurately called, "didactic" teaching should be abandoned. The discussion as carried on in medical journals, appears to lean in this direction. A course of systematic lectures enables the teacher to cover ground which he would be unable to do, even in a clinic most richly endowed with material. The method of handling the subject differs entirely from that adopted at the bedside, and in a well regulated four years' course I believe the systematic lecture should still retain a prominent place. Clinical instruction should be abundant and of the most varied kind. Instruction of the class in small sections is a most desirable feature of this department. It involves a greater expenditure of time, an increase in the teaching staff and great ability as an organizer in the head of the department. It is the squad drill, however, which brings the student in most intimate contact with disease.

To carry out these ideals necessitates a "plant" far in advance of that which the average school now possesses. No such enterprise can be undertaken without that aid which has hitherto been conspicuous by its absence. I refer to endowments; the valuable paper of Dr. Bayard Holmes already referred to gives some interesting data on this subject. He says:

"The productive funds in the hands of medical schools, both those connected with and those independent of universities in the United States was in 1889, \$249,200, while at the same time there was in the hands of schools of theology productive funds to the amount of \$11,839,931. The value of buildings and grounds used by medical schools at the same time was \$1,047,618, and the theological schools were accommodated with buildings and grounds valued at \$7,762,095. The medical schools had in 1889, 12,238 students who paid tuitions to the amount of \$763,761, while at the same time the theological schools enrolled 6,959 students.

I am able to reinforce these figures by an abstract of the statistics for medicine, theology and technology as reported to the Bureau in June, 1892. The medical schools possessed buildings and grounds in 1892 valued at \$7,507,337, and productive funds amounting to \$611,214. Medical departments of State universities also received State aid in 1892 amounting to \$40,500, which, if capitalized at 5 per cent., would be equal to an endowment of \$810,000; making a total endowment of \$1,421,214. There were 16,731 medical students in attendance.

The theological schools report productive funds amounting to \$17,599,979, and stated, at the same time, the value of their buildings and grounds was \$10,720,860. They had 7,672 students in attendance.

Technological schools report productive funds amounting to \$13,229,940. These institutions received from State appropriations or municipal aid in 1891-92, \$747,594, which, if capitalized at 5 per cent., would be equivalent to an endowment of \$14,950,080; making a total endowment for schools of technology of \$28,180,020. There were enrolled in the schools of technology 10,921 students, about one-third of whom were in preparatory courses. It will thus be seen that the endowment of theology is increasing at the rate of about two million dollars a year. The technological schools are well provided for, but medicine has scarcely raised its endowment, even at the most liberal estimate, to a million and a half."

Probably the available funds possessed by our medical schools are somewhat larger than these statistics show, but they give the proportions which are needed to impress upon us how little financial encouragement medicine receives. When we realize what a valuable factor the medical man is in the rapidly increasing development of the territory of a vast and prosperous country like ours, it seems as if his claims to receive encouragement should be listened to. He does not build railroads or organize society in new lands, but he is in the foremost rank of pioneers, with the complete equipment which our teachers can give him to-day, and he becomes a most valuable member of society. He protects the young colony from epidemics; without him State medicine could not exist, and States could not be provided on a basis which could ensure prosperity.

These ideas should be impressed upon our men of wealth and upon the State governments as well. In the meantime it is important that we should adopt as a principle in our new departure in education that the medical faculty should have personal control of hospital wards and management. Let this work begin in a small way at first, but with a view to future development. Such a change can only be brought about by a slow process of evolution. The sooner, therefore, the principle is recognized and adopted, the better. It is difficult for a prosperous school which has abundant opportunities for bedside teaching to realize this, but it can not develop beyond a certain point until it has established its own independence.

I cannot help believing that in this direction lies one of the greatest avenues of development of our system of medical education in the future.

ADDRESS OF THE PRESIDENT OF THE SECTION ON NEUROLOGY AND PSYCHIATRY OF THE PAN-AMERICAN MEDICAL CONGRESS.

BY C. D. HUGHES, M.D.

ST. LOUIS, MO.

Collapses of the Continents.—I bid you cordial welcome. For the first time in the history of the world the medical profession of all the Americas meets fraternally for mutual work and words of counsel for the welfare of the North and South American medical profession and people.

In this Neurologic and Psychiatric Section, brothers, we also, for the first time, grasp the hand of fellowship. We heartily clasp hands with you and in our hearts we embrace you, with the prayer

that nothing shall ever dis sever the friendship between the Northern and Southern American profession now so auspiciously consummated. May the final handshake between the profession of the North and South American States never be permitted to take place. We want your friendship forever. So long as "earth grows a plant or sea rolls a wave," we pray that it may endure, growing closer and closer in ties of inseparable fraternity.

In our special departments of medical research and labor we have a common interest, and in every department of medical investigation and advance, our interests are likewise mutual. The sanitary welfare of all the American States is alike. The same hygienic, therapeutic and pathologic problems press upon us all for solution; the medical discoveries of each one of these States redounds to the welfare of all the others.

To this end, therefore, we salute and welcome you, wishing you health and happiness, through a mutually advanced and glorified medical profession, and in behalf of the Neurological Section of this great Congress, I join you in the sentiment, "*America laudamus—rica Americana.*"

Before proceeding to the work before us, it may prove a source of pleasure and profit, and it certainly is flattering to our professional pride to note some of the neurological advances of our day and especially the contributions of neurology to general medicine and the consequent welfare of the world.

None of the many victories in the onward march of American medicine during the century now nearing its close, have contributed, or are destined yet to contribute, more to the happiness of mankind than the light which has been thrown on the nature and treatment of inebriety, dipsomania and chronic alcoholism and their neural sequelæ, especially multiple neuritis.

To a distinguished American physician, signer of that Declaration which gave a nation birth, surgeon-general of the Continental army and teacher of the practice of medicine in the first medical university founded in America, Dr. Benjamin Rush, the scientific world is indebted for having taught that inebriety is a disease. His followers, living in the Pan-American States, taking their cue from this distinguished pioneer medical *savant*, have pursued the study until the therapeutics of inebriety has become as successful as that of any other grave nervous disorder and its pathology as well understood, while medical philanthropy, following his advice, has erected hospitals for the cure and care of its unfortunate victims, though, as yet, no monumental shaft mementos, as it should, a nation's grateful memory of Benjamin Rush's noble work.

We record, also, with satisfaction scarcely exceeded by that we enjoy from contemplating the salvation of the inebriate, the successful cure of the opium habit and other kindred forms of baneful drug enslavement. Yet it has not been long since that once brilliant *littérateur*, De Quincy, himself enthralled, proclaimed in despair the "pangs of opium" and the "Iliad of woes" its enslaved victims hopelessly endured.

The opium fiend, as he is with cruel facetiousness so often called, need not be longer regarded as a hopeless wreck if the hand of charity will only conduct him within the pale of professional resource.

This and alcoholism and all similar forms of nervous derangement are now treated successfully much like certain forms of mental aberration are—by change of environment, by therapeutic repression, including hypnotic support and reconstruction of the damaged and aberrantly-acting neuropsychic centers. This is another jewel medicine offers for the crown of modern progress.

Notwithstanding the illustrious names which, in our own day, the world beyond our geographical boundaries has given to medical science, our American States have likewise their great physicians whose offerings on the altar of that science whose special care is the welfare of man, are worthy of exalted place beside the Old World's gods. For the Virchows, Charcots and Lombrosos, Maraglianos and Kowalewskys, Gulls and Horsleys, of world-wide fame beyond our shores, we have given to the world our Brown-Séquard, who went from America to cosmopolitan fame; our Hammond, another pioneer American neurologist whose books have been translated into all the languages of civilization; our Seguin likewise, and our Pepper, President of this Congress and the peer of Sir William Gull of Great Britain, and Ferran, whose preventive inoculations against cholera Asiatica called the medical world's attention anew to the grandeur of Spanish medicine. If Wigan could conjecture the duality of the mind from theoretical considerations and the general division of the brain into hemispheres, Brown-Séquard later, and at the time an American, proved it, and even my own feeble contribution on the "Duality of Action and Vicarious Functions of the Cerebral Lobes and Hemispheres," in 1873, might count for something, even though it emanated from a lunatic asylum in the valley of the Mississippi. If Hitzig, a German, and Ferrier, an Englishman, demonstrated and located motor centers in the cerebrums of the lower animals, Bartholow, an American established by satisfactory physiological experiment their correspondence in the human brain.² If Victor Horsley and others first clinically applied the discovery of cerebral localization to surgical therapeutics for brain diseases, Professor William Fuller, a Canadian anatomist and surgeon, first trephined the skull in a case of idiocy, an operation which has recently been heralded from abroad as a new surgical procedure.

The author of this operation, now residing in this country, in Grand Rapids, Mich., is the designer from life of a series of brain sections and sectional casts, photographs and models, some of which I now show you, which have not been excelled in Europe.

Now that this operation of Dr. Fuller has come back to America with European approval as a European procedure, it is interesting to note the reception, a part at least, of the medical press of England, gave the novel surgical procedure at its inception on this continent.

The following extract from *The London Doctor*, a monthly review of British and foreign medical practice and literature, No. 1, Vol. 8, page 5, January 1, 1878, is appended as evidence that the case reported in this paper, received at the time a wide publication:

"Dr. Fuller of Montreal, has, says the *Canada Lancet*, conceived the novel idea of trephining out portions of the skull

of an idiot child of two years old, so as to allow the expansion of the brain. The idea is certainly novel, so far as we know, no surgeon having previously ventured to remove portions of the skull cap so as to allow the brain to expand. We sincerely hope this brilliant experiment will not be repeated. How does Dr. Fuller propose to protect the exposed portions of brain, should the brain protrude through the apertures he has made? According to latest advices, Dr. Fuller contemplates removing another piece. We hope not."

Under the name of linear craniotomy, this operation has recently found decided approval both at home and abroad. Engel speaks enthusiastically of it even for dementia epileptica.

If European surgery first excises a stomach, or a kidney, or cuts down upon and removes a stone from the bladder or gall cyst, American surgery, represented in the person of Ephraim McDowell, with a temerity that startles the conservatism of Europe, first cuts into that surgical terra incognita, the abdominal cavity and saves an imperiled human life by successfully removing an abdominal tumor; a feat common enough now, alas, all too frequently performed by novices with the knife, lacking in mature surgical judgment. He and Battey, another American, led the way for the successful ovariectomies of Lawson Tait and his followers, and Marion-Sims. God bless his gentle, precious memory, lays the foundation, by a peerless procedure on the female perineum, for the rescue of womanhood from untold misery. Marion-Sims, who, when asked to unsex a woman, in whom there was other possibility of salvation, could say to Weir Mitchell, "Let us give her a reprieve; I never unsex a woman without a pang," and the woman got well as you and I know hundreds of others would, if permitted to do, without oophorectomy. God bless Marion-Sims.

As we are justly appreciative of the part which American skill has performed in the world's surgical advancement; as the recalling of the names and deeds of our Motts, Brainards, Popes and Stones and Physies, Gross and Hodgins, gives us pleasure; if we revere our Rushs and Woods as England does her Hunters, Sydenhams and Gulls, so of our own American alienists and neurologists and their achievements, we are justly proud. The accomplished Isaac Ray and the gifted Amariah Brigham, Pliny Earle and Tyler, now no longer among us, and Van Dusen, the son of Michigan and a Kalamazoo asylum superintendent, whose essay on "Neurasthenia" preceded that of the classic work of Beard on "Nervous Exhaustion"—Beard who gave to the world a new disease, and gave it a new name, although the term "neurasthenia" was borrowed unknowingly from Van Dusen (*ride Alienist and Neurologist*, Vol. I, No. 4, 1880). Since these contributions appeared, the subject of nervous exhaustion has become too common in the literature of this country and Europe to need further mention here.

There are three works of Dr. Hammond which have had much influence on neurology and medicine generally, and these were accomplished during his service as surgeon general on the active list of the United States army:

1. The establishment of the Hospital for Injuries and Diseases of the Nervous System in Philadelphia, where the foundation of Dr. Weir Mitchell's most original work, "Wounds and Injuries of Nerves" was laid, Dr. Mitchell having been placed in charge by Surgeon General Hammond.

² American Journal of Insanity, Vol. XXXII, 1875.

³ American Journal of the Medical Sciences.

2. The establishment of the Army Medical Museum in Washington.

3. The origination of the "Medical and Surgical History of the Rebellion."

These three things give our colleague just claim to distinction. I think the Hospital for Nervous Diseases was the first of its kind ever established in the world. Besides, our colleague wrote the first systematic "Treatise on Diseases of the Nervous System" in the English language, if not in any language.

If we look for discovery and classification of disease, America has not been entirely wanting. For a long time Beard's claim was controverted abroad; afterward neurasthenia was called "the American disease," then "American nervousness," till finally foreign writers recorded it among their people, even away off in far-off Russia, where Kowalewsky has written his classic book on the subject and given us due credit for our discovery. So in regard to Hammond's discovery of athetosis and mysophobia, and the coinage of these terms; and in regard to neurasthenia, I believe it is even now conceded that the original American claim¹ of general functional neurotrophias as the foundation of nervous exhaustion is universally admitted.

Seguin, in his clinical lectures in 1890, first suggested the substitution of a mixture of chloral and bromid for simple bromid, in the treatment of idiopathic epilepsy, when certain indications are present, chloral being indicated when the bromids alone produce undue stupor and extremely severe acne; also in cases where psychic disorder follows the stoppage of the bromids. This practice has now become general. He first attempted to subdivide the symptomatology of "cerebral hyperemia" (of Hammond and others) into several new groups according to etiology, e.g., cases due to lithemia, to feeble or diseased heart, and (a large group) to eye strain, etc. He also attempted to give the distinguishing clinical signs (*N. Y. Med. Jour.*, Dec., 1892), between cases of cerebral paresthesia due to insufficiency of the interni, and those due to insufficiency of the externi, and recommended the use of nux vomica and strychnia for weakness of the interni and of belladonna, cannabis indica and other mydriatics for weakness of the externi. These drugs to be used as tests for diagnosis, and also for continuous treatment. He contributed by autopsies and clinical cases to confirm the doctrine of cortical localization of functions, in respect to the visual center (cuneus, in 1880, I think); the speech center (1868); and in subsequent years the facial, brachial and pedal, or crural, centers, and gave absolute postmortem evidence in support of the idea that such centers exist.

Besides Bartholow's communication, the whole subject of cerebral localization has received additional light from the contributions of our Charles K. Mills, of M. Allen Starr, Eskridge, Spitzka, myself and nearly every American neurologist, while the contributions of the latter to cerebral pathology, as those of Isaac Ott to cerebral physiology, have been justly acknowledged abroad.

Seguin and Hammond early advocated before any one else abroad, I think, the use of large doses of potassium iodid in syphilitic or non-syphilitic diseases of the nervous system, giving historical proof of its American origin (New York) and called it the "American method." Attempts have been lately

made in Europe to ignore our great priority in this. Seguin says he learned it from Van Buren and Draper in 1865-7. I adopted this practice at the insane hospital at Fulton in 1867-8.

It falls to the lot of but very few men to discover a really important thing and to cause a great forward step to be made in medical science. Most of us must be content with helping the good work of adding new facts of secondary importance, and trying to apply scientific methods to the treatment of disease. I think that in this sphere of secondary scientific usefulness, American neurologists have made and are making good records.

The clinical relation of absent patellar reflex to locomotor ataxia, though first shown by Westphal and Erb, was extensively studied by Seguin, Gray, myself and others, and its relation to other diseases and the possibility of the knee-jerk being naturally nil in some persons was first shown in this country and acknowledged abroad,² so that the knee-jerk criteria of tabes dorsalis is a lost reflex, and an exaggerated jerk in lateral sclerosis and other states. I myself offered the first proof many years ago that it need not be present in apparently healthy individuals. One of those persons still lives and is free from any spinal or other nervous disease to this day. What is true as to elucidation of this reflex is equally true of the cremasteric and other reflexes, *vide* writings of Weir Mitchell and others. The bulbo-cavernous reflex and the virile reflex, practically the same thing, were discovered and clinically elucidated about the same time in Europe and America.

The value of the cremasteric reflex has been studied by Weir Mitchell with the same thoroughness of elucidation as that he has given to lesions of the peripheral nervous system generally; and Dr. John Ferguson of Toronto, Canada, has also thrown new light upon the patella reflex (*vide* "Remarks on Some Cases of Hemiplegia," *Alienist and Neurologist*, January, 1892). This subject has also lately been enriched in this country by Dr. F. X. Dercum, in a paper on "Optic Neuritis, Blindness and the Knee-Jerk in Cerebellar Disease," read before the American Neurological Society, July 25th.

The important subject of rheumatism affecting the nervous system was embodied in the recent address of Dr. Henry M. Lyman, before the American Neurological Association, and attention called to important clinical facts, especially affections of the sensory nervous system, not commonly recognized as associated with this disease.

The gastralgias, enteralgias, cutaneous irritations, sensitive feet and arthritic and cutaneous neuritides of rheumatism, have often attracted my attention, and have been to me an interesting clinical study, and much more is yet to be written on this important subject.

In the therapeutics of the nervous diseases, as well as in clinical description and pathology, to America belongs much credit for originality and efficiency of discovery and suggestion. Was it not in this country that the great Brown-Séquard first conceived and promulgated his famous treatment for epilepsy, which has done more than all preceding or subsequent therapeutics suggested for the alleviation of this grave malady?

¹ "Diagnostic Significance of Absent Patellar Reflex."—*Alienist and Neurologist*, January, 1890; *St. Louis Medical and Surgical Journal*, February, 1879.

All the now acknowledged virtues of *phytolacca decandra*, or poke root, except the property of *phytolacca* to reduce corpulency, were brought to my attention through the thesis of a student candidate for graduation of the St. Louis Medical College in 1859; and Dr. Bealle, a fellow-graduate with me that same year, from Texas, told in a thesis, which he entitled "Ups and Downs of a Texas Doctor," how he made a satisfactory flexible bougie out of green slippery elm bark, how he employed a smooth green wheat straw for a catheter and the crushed potato-bug mixed with lard as a satisfactory vesicant in lieu of Spanish cantharides—practices which I imitated myself while doing a general country practice in Missouri in 1859 and '60, when I could do no better, and there is nothing much better for gentle dilation in certain surgical emergencies than a smooth slippery elm bougie. I could relate other instances of western American surgical genius in the use of therapeutic expedients in pressing emergencies of practice were they strictly germane to our subject.

I claim the credit myself of having first suggested and used in private practice chloral hydrate per rectum in the treatment of convulsive affections, a method based on the West Riding asylum practice in epilepsy, and used by me for arresting the convulsions of children and of the puerperal state.

Leonard Corning's method of local anesthesia is original and we justly claim the discovery and therapeutic application of general anesthesia as American, Sir James Y. Simpson, to the contrary notwithstanding. Copious ether douching for cephalo-spinal pain was practiced by myself thirty years ago. I was the first to employ capsicum, hot coffee and ammonia enemata to resuscitate from profound opium narcosis (*vide Appendix*), after failing with a battery. Kiernan was the next to follow the practice.

In the department of electrotherapy, especially in diseases of the nervous system, America stands well forward in therapeutic suggestion and resource. Beard and Rockwell and their followers in this country have done much in this line. It has been fully thirty years since I first employed the constant current for cerebral and other congestive states, not excepting ovaries and pelvis, and recommended it in gynecology, based on a prior recommendation of Legros and Onimus that it would reduce inter-pelvic sanguineous fluxes. It has been more than twenty years since I began the systematic employment of constant cephalic galvanizations for the cure of insomnia and the treatment of epilepsy, under the conviction that the prominent symptomatology of both of these affections were dependent upon disorder of vasomotor control, which cephalic galvanizations tend to restore as the bromids do. But I must not speak further of myself.

In this connection I may properly mention Dr. Henry M. Lyman's book on "Artificial Anesthesia and Anesthetics, Insomnia and other Disorders of Sleep," as a valuable American contribution to these subjects.

We have done no markedly original work in hypnotism, but have some imitators of Charcot and others, as Charcot and his followers have with professional applause followed Braid, the professionally tabooed Manchester follower of Mesmer, the mount-bank original.

Cataphoresis in neurotherapy has been considerably advanced in America by Corning, Peterson and

others, and likewise the hypodermic use of arsenic by Moyer; also the employment of antipyrine, acetanilide and other coal tar derivatives, by the last named and many others. (*Vide Appendix*.)

The therapeutics, as well as semiology, of insanity has been enriched by Jewell and Moyer in this country, by treatment directed to the colon. (*Vide Appendix*.)

Nitroglycerine, or glonoine, was first suggested to the regular profession in 1876 and '78, by Allen McLane Hamilton, before Murrell or others abroad had used it, for anemic cerebral states and cerebral arteriole spasm. It was on this recommendation and the recommendation of nitrite of amyl for a similar purpose, that I first employed the latter for the differential diagnosis of supposed hyperemic from anemic intracranial states. (*Vide editorial in Hygienist and Neurologist*, October, 1880.)

A decidedly original and successful procedure in American surgical neurotherapy is that of pudic neurectomy as a remedy for masturbation, reported by Dr. J. S. Eastman in the *Medical News* of August 12th, of this year. The nerve being more sensitive on this side, Dr. Eastman cut down upon the left pudic nerve, which he found hypertrophied, and removed three inches of it. The patient gained weight and was freed from this vice, which had existed from the sixth to the twenty-sixth year. She had been previously sutured in the labia, cauterized, oophorectomized and clitorrectomized without benefit.

Veratrum viride, one of the very best remedies I know of for sthenic states of high cerebral and pulmonary congestion with full, bounding pulse and violent cardiac systole, is better than the lancet in high grade apoplexy and pneumonia, as it is fatal to apposite asthenic states of pulmonary inflammation and cerebral congestion, is a distinctly American remedy, and the practice of using it, as well as abusing its use, is of American origin. It may sometimes well substitute the bromids in certain phases of neurotherapy. I have so employed it. But we must not further dwell specially on American original contributions to neurotherapy. We could not complete the subject in the limits of an ordinary duodecimo volume, while another volume of equal size would not record the real practical progress and unequaled elegance of American pharmacy as applied to our therapeutics.

In the direction of neurological originality and advance, the work of our own distinguished Spanish-speaking secretary, Dr. M. G. Echeverria must not be overlooked. Though his modesty has prevented him from publicly claiming his due reward of merit, his claims have not been overlooked by foreign sources of appreciation.

His English publications, notably his great book on "Epilepsy," although scarcely noticed by American authors, are much and favorably quoted by neurologists in Germany, England and France. On their merit he was elected honorary member of the Medico-Psychological Society of Paris, and of Great Britain and Ireland; also vice-president to the first *Congres International de Medecine Mentale*, held in Paris in 1878, when he was called upon to preside on motion of the late Prof. Lesegue, after the sudden illness of Dr. Baillarger, chairman of the congress. So far as I know, Dr. Echeverria was the first physician in this country who, as "Professor of

Nervous and Mental Diseases," delivered didactic courses or lectures on this subject. This was in 1861, in the University Medical College of New York, while Seguin followed at the College of Physicians and Surgeons, in 1873. On his removal to New York from the National Hospital for the Paralyzed and Epileptic, in London, where he had occupied the position of resident assistant physician with Drs. Brown-Séquard and Ramskill as visiting physicians, he induced the Commissioners of Public Charities and Correction to establish the Hospital for Epileptics and Paralytics on Blackwell's island, New York, under his chief direction, and to found a school for idiots in Randall's island. Dr. E. Seguin, *père*, Drs. Kerlin and Wilmarth, of Elwyn, in their literary and practical works as revealed in the pages of the *Alienist and Neurologist*, *vide* Appendix, Dr. Brown of Barre, Mass., and the Wilburs have certainly done much creditable pioneer work with this class of defectives.

We may here remark, as facts of historical interest, that Dr. Echeverria was the first in America to perform, in 1865, assisted by Dr. J. H. Douglas, excision of a large portion (two inches) of the ulnar nerve at the elbow for the radical cure of epilepsy following upon traumatic injury. In 1869, in the presence of Prof. Boeck of Christiania, and other physicians and students, he removed at the hospital in Blackwell's island, the largest sanguineous clot (one and three-fourth inches long by three-fourths of an inch wide) ever extracted, to that time, from the base of the second parietal convolution of an epileptic lad, another operation lately originated abroad. The conical fibrinous clot was deeply imbedded in the cerebral substance, and the patient directly recovered his lost intellectual faculties upon the successful operation. The case is reported in his "Clinical and Anatomopathological Researches on Epilepsy," and in a subsequent paper published in Paris in 1878 (*Lesquin's Archives Gênerales*), with the records of five similar cases from Dr. Echeverria's own practice, and one hundred and forty, mostly by American and English surgeons. This paper was written mainly to show how unwarranted was the risk of this procedure then ascribed to it by French surgeons.

This distinguished neurologist, one of our colleagues, to-day, and those I have named before him, will not be overlooked when a candid world enumerates in history America's neurological benefactors.

Worthy of special mention with the foregoing is our indefatigable co-worker and colleague, Prof. Chas. K. Mills, whom the University of Pennsylvania has so lately honored with its chair of mental and medical medicine. His recent studies in "Lesions of the Superior Temporal Convolution," accurately locating the auditory center, his presentation of the subject of aphasia and other affections of speech in their medico-legal relations, and lesions of the cauda equina, are real advances that must be universally acknowledged, as are likewise the complications of multiple neuritis and other papers, which we present in the appendix.

And now I name another star which shines in the neurological firmament of New York—a star emphatically spelled by his far-seeing parents with a double

book on "Brain Surgery" (published by Wm. Wood & Co., New York), he has given us a special study of "Local Anæsthesia as a means of Diagnosis of Lesions of the Lower Spinal Cord" (*American Journal of Medical Science*, July, 1892); "The Cerebral Atrophies of Childhood, with Special Reference to Imbecility, Epilepsia and Paralysis" (*N. Y. Medical Record*, Jan., 1892); "Trephining for Hemorrhage of the Brain Producing Aphasia—Recovery" (*Brain*, 1892); "Hemi-Anæsthesia Alternans" (*N. Y. Med. Record*, Feb. 11, 1893), and has thrown some new light on the subject of "Syringo-myelia" (*vide American Journal of Medical Science*, May, 1888). His book, "Familiar Forms of Nervous Disease," is a credit to any country. Other bright neurological stars are shining, and many have shone longer, in the same scientific and humanitarian sky.

It is my impression that Ord's discovery of myxœdema received its first clinical confirmation in this country, and McLane Hamilton, I think, furnished five of the earliest clinical proofs of its verity as a distinct disease.

Hamilton first pointed out the neuro-genesis of certain meningeal inflammations, and I have maintained and do yet maintain that hemophilia is a vasomotor neurosis.

The *Alienist and Neurologist* (April, 1884, *ad seq.*), early maintained that oophorectomy was too often performed, upon the mistaken assumption that the ovary originated nervous disease, whereas the reverse is the most common clinical fact. This is not only an original American claim, but it is now becoming a generally admitted fact both abroad and at home, and the latest and best articles on this subject are by Dr. Hamilton.

Another rising luminary of this field is Dr. Frederick Peterson, a reference to whose late contributions (*vide* the Appendix) will interest you and show some good spokes, at least, in the wheel of neurological progress. His recent papers on "Cataphoresis," his physiological experiments with magnetism at the Edison laboratory, and his joint papers with Sachs on "The Cerebral Palsies of Early Life" (*Jour. of Nervous and Mental Diseases*, May, 1890), and other papers to be found in Appendix, are all valuable.

But the stars of this firmament are too many to be counted. Should we dwell long enough to attempt it, we should not during our hour get round the circle. There remain Sachs, who has translated Maynert's "Psychiatry" for us; Bert Wilder, "The Brain Builder of Ithaca"; A. Jacobi, "The Universal Genius"; Corning, already mentioned, whose book on "Brain Exhaustion" is standard. There is also Dana, to whom we have already alluded, with Carter Gray, whose respective books are abreast of all neurological advance, and in every way creditable to American neurological science; besides E. N. Brill, Graeme M. Hammond, and Brown of the *Journal of Nervous and Mental Diseases*; also Ambrose L. Ranney and his standard textbooks on "Nervous Diseases and Neurological Anatomy," and Geo. I. Stevens with his Belgian Academy prize essays on the "Oculo-Neural Reflexes, and the Relation of Eye Strain to Nervous Diseases," whose first article on this subject appeared in the earlier numbers of my journal. Too many stars to classify and minutely describe, but they make a brilliant constellation.

If we look back to Philadelphia we discover another neurological star that has escaped our gaze, Wm. C.

Among numerous recent contributions, besides his

Wood, whose treatise stands high, and yet another, Dr. A. H. P. Leull, of neuro-anatomical fame, also Harrison Allen. There is Wormly, too, of Philadelphia, who is not altogether without the pale.

Far to the southward are Joseph Jones of New Orleans, and Buckley of the occidental metropolis.

And now, casting our eye to Baltimore, our vision falls on three luminaries, Miles, Osler and Hurd, whose light has not shone in vain; there also shine Conrod, Reed, Berkley, Welch and Halstead of Johns Hopkins hospital.

Skirting the sky northward we come to the Hartford constellation, Stearns and Crothers. The book of the former is devoted to practical psychiatry; the contributions of the latter to that important branch of psychiatry which, through Mason, Wright, Crothers and others has made such rapid forward strides in America, as well as in England, the study of inebriety.

The subject of alcoholic trance has been almost exclusively an American neurological study, and Dr. Crothers has contributed more than any other American, perhaps, to make it plain. In the Appendix appear further evidences of American advance in this direction:

"Law of Periodicity in Inebriety" (*vide Alienist and Neurologist*, July, 1892), showing a uniformity in the drink impulse and the laws which regulated it.

As our vision ranges further, Boston, with its neurological and psychological *savants*, comes into view—Philip Coombs Knapp and his book on "Intra-Cranial Tumors and Other Diagnoses;" Putnam, Channing, Webber, Folsom; John E. Tyler, the departed alienist of Somerville, and Oliver Wendell Holmes, the poet sage and anatomical and psychological *savant* of Harvard. The subject of "Arterial Tension in Neurasthenia" received some new light from Boston in 1888 (*vide* article on the subject by Webber, *Boston Medical and Surgical Journal*, May 3, 1888); likewise the subject of "Lead Paralysis as it Affects the Brain" (*vide* same source, October 29, 1891); also the "Condition of the Blood in Certain Mental States" *vide idem*, March 24, 1892). The same journal for August 29, 1889, also contained some additional light on "Paramyoclonus Multiplex," and other peculiar forms of spasm, and in September of the same year, in same journal, page 277, this American writer throws additional light on the subject of "Cerebral Tumors and Their Treatment."

As we continue our survey of the neurological heavens, we come to the constellation Chicago, with such bright, particular, neurological stars as Lyman, with his book on "Practice;" Kiernan, the polygot; Moyer, the tireless; Paoli, Sanger, Brown, Brower, Clevenger, Lydston, and their books, and Church,—sadly remembering one bright luminary of these heavens now blotted out, whose light shone for a time upon our particular sky with effulgent luster—Dr. J. S. Jewell. He was a star of the first magnitude, a neurological Jewell of the first water, an indefatigable student, a painstaking observer, and a writer of the highest ability.

He blotted out his own bright life in the prime of his manhood by over zealous work in the cause he loved above his life. He founded and maintained while he lived the *Journal of Nervous and Mental Diseases*. And this reminds us that we should not omit most honorable mention, in this connection, of the name of Dr. Jewell's worthy and industrious co-worker, Dr. H. M. Bannister, among the men of might

in Chicago who have contributed to brighten her brilliant neurological sky.

Moyer has contributed a paper for the advancement of clinical neurology not already referred to: "Clonic Rhythmical Spasm of the Pronator Radii Teres" (*JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, 1887); "Periodically Recurring Oculo-motor Paralysis" (*The Medical Record*, 1887), being the first case described in this country; "Akinesia Algeria" (*Medical Standard*, 1893), being the sixth case reported, and the second in this country; and "A Rare Occupation Neurosis?" (*Medical News*, 1893). By his works ye shall know him (*vide* Appendix for much more than we have here noted).

Within almost a suburban radius of Chicago is McBride of Milwaukee, and his "Review of Insanity and Nervous Diseases."

Modesty forbids my dwelling at length upon what St. Louis has done for the advancement of neurology. We may recover from our modesty sufficiently to appear in the printed Appendix; however, I might briefly intimate that both Dr. Bremer and myself have within the past few years added something to the literature of "Astasia-Abasia;" Fry to "Chorea;" Shaw to the subject of "Trapping for Brain Disease," and Bauduy to the "Study of Alcoholism and its Treatment." This is not all that we have done; but it were better that some one else, non-resident, should record and comment on our work, and I may say again, as I have said before (*vide* Appendix).

Now, if we continue our survey, we find the sky of neuriaty and psychiatry is not dimmed as we approach the region of the apparently setting sun. On the contrary, bright stars illuminate the western heavens. See how Eskridge shines:

He has contributed a valuable paper on "Nervous-Vascular Disturbances in Unacclimated Persons in Colorado" (*The Climatologist*, March, 1892); the important conclusion of which is for persons on going to the high altitudes of Colorado, especially for those who are nervous or who suffer from pulmonary trouble or cardiac weakness, to live comparatively quiet, until they become accustomed to their changed environments.

Likewise another on "Chorea in Relation to Climate, Especially the Climate of Colorado" (*Climatologist*, August, 1891). This study of the effect of the climate of Colorado on chorea shows but little, if any, modifying influence due to altitudes of 5,000 feet to 6,000 feet.

Another exceedingly valuable and advance contribution to the literature is "Retro-Anterograde Amnesia, with Report of Two Cases" (*Alienist and Neurologist*, July, 1892). This is an exceedingly interesting subject, both from a psychological and medico-legal point of view.

This is as far as we can go with Eskridge. But he has written much from his high standpoint in the Rocky mountains, and all is in the line of advanced neurology. (*vide* Appendix.)

Next comes Howell T. Pershing of Denver, who records five cases of pre-ataxic tabes dorsalis with optic nerve atrophy in which there were marked atrophy of the optic nerves with little or no ataxia. He gives a statistical study of tabes, and shows that (as Walton and Gowers have recently claimed) the early occurrence of optic atrophy is in some way associated with an arrested development of the spinal symptoms.

This fact modifies the ordinary rules of diagnosis and prognosis.

He also records a case of Jacksonian epilepsy, with successful operation; no recurrence of the paroxysms more than a year after operation. Other articles by this writer are: "Language and Brain Disease" (*Popular Science Monthly*, October, 1892), and "Disseminated Sclerosis following Syphilis" (*International Clinics*, July, 1891).

But we cannot go farther in this manner. If we went hence south to the City of Mexico, thence across the gulf to New Orleans, thence north to St. Paul and crossed the continent to San Francisco, we should find working neurologists contributing their quota to the world's neurological and psychological progress.

As I am about to conclude, the proceedings of the July meeting of the American Neurological Association have just appeared in the weekly medical press, and here are its notes of American neurological progress:

Besides the President's Address and Dr. Dercum's paper, to which I have referred, Dr. Smith Baker's paper on "Heterogeneous Personality;" Matthew Field's on "Hospital Detention;" Frederick Peterson's on "Temperature in General Paralysis of the Insane;" Joseph Collins' on "Changes in the Spinal Cord in Old Cases of Infantile Paralysis;" G. M. Hammond's of "Progressive Muscular Atrophy;" C. L. Walton's "New Method of Reducing Dislocation of the Cervical Vertebrae;" Dana's "Acromegaly, Gigantism and Facial Hemi-hypertrophy;" J. J. Putnam's "Thyroidectomy in the Treatment of Graves' Disease;" B. Sachs' "Tubes and Syphilis;" Kraus' "New Pedodynamometer;" Drs. Lloyd's and Reisman's joint communication on "Infectious Endocarditis with General Septicemia and Multiple Neuritis;" C. L. Walton's "Tumor of the Angular Gyrus;" Dr. E. D. Fisher's "Autopsy and Report of Congenital Cerebral Hemiplegia;" C. K. Mills' "Lesion of the Thalamus and Internal Capsule;" Wharton Sinkler's "Tumor of the Optic Thalamus;" Geo. J. Preston's paper on the "Localizing Value of Aphasia;" Leonard Weber's on "Neurasthenia;" Kraus' "Case of Myxedema, with Observations;" Philip Coombs Knapp's "Simulation in Traumatic Nervous Diseases;" and "The Microbic Origin of Chorea," by Dr. C. L. Dana, are all instructive, suggestive and progressive in our department. The proceedings of this favorite American society are becoming every year more and more valuable. They are indispensable to neurological advance. The neurological world would not march on to its manifest destiny to rule paramount in the world's medical thought without the original work of this great American society of distinguished neurologists.

There were also papers read only by title before this body, the names of whose authors are also adequate warrant of worth. Among them—"The Genesis of Hallucination and Illusion," by H. A. Tomlinson of St. Peter, Minn.; "The Diagnosis of General Paresis," by L. C. Gray of New York; "Two Cases of Friedreich's Disease," by F. R. Fry of St. Louis; "The Metapore or Foramen of Majendie in Man and in the Orang-Outang," by Bert G. Wilder; "The Relations of Chorea to Rheumatism," by C. Eugene Riggs of St. Paul; "Experiences in the Use of Testiculin and Cerebrine," by J. J. Putnam of Boston; "Paralysis after Surgical Operations," by V. P. Gib-

ney of New York; "Traumatic Brachial Plexus Paralysis in Infants," by Wm. Leszynsky of New York.

If I should go on enumerating the work, present and recent, of American neurologists, it would develop acute cerebraesthesia. It would make you tired.

I had almost forgotten to note the contributions of our hospitals for the insane to the pathology of mental diseases. I cannot now go entirely over this vast subject. Besides what has been done at Utica, N. Y., and Middletown, Conn., with which you are familiar through the *Journal of Insanity*, you may not know that it has for a long time been the custom of Dr. J. W. Blackburn, the eminent pathologist of the Government Hospital for Insane, at Washington, to each year select a number of cases for special study as a pathological supplement to the annual reports of the Government Hospital for Insane. This and the making of nearly one hundred post-mortem examinations yearly, constitutes the work of this hospital, to which I also invite your attention in the Appendix.

You see, America breeds and develops neurologists as the water breeds and develops fishes. The pabulum neurology feeds on is in the American people—their hustling, rushing habits, their business, professional, social and political environment, and the numerous newspapers they read every morning before breakfast and every night before they forget to say their prayers—this moral, political, social and business atmosphere of ambition and bustle, tends to develop the strongly endowed, neurologically and psychologically, as it tends in the weakly endowed to the development of neuropathic conditions. It develops neurologists and psychologists to care for the neuropaths. It builds and it breaks the nervous system. It can not yet be said that we are a neuropathic people, though we are tending that way; but neurology is advancing with equal pace with neuropathic break-down, and will, it is hoped, ultimately enlighten and save the people from their neuropathic sins.

ADDRESS.

BY E. FLETCHER INGALLS, A.M., M.D.

CHICAGO.

EXECUTIVE PRESIDENT OF THE LARYNGOLOGICAL SECTION.

Gentlemen and Colleagues:—In calling to order the Laryngological Section of the Pan-American Congress, I take the opportunity to congratulate you upon the number and excellence of the papers which have been secured for your consideration.

I feel that there is a special reason for felicitation upon the propitious circumstances under which we have convened, because of our success in spite of many obstacles.

The laryngologists of this country as well as those who would have visited us from abroad, have been called upon for more than the usual amount of work during the past few months. Early in May the American Laryngological Association met in New York and was largely participated in by those who otherwise would have been free to aid us. Shortly afterward the American Climatological Association met in Philadelphia, taxing the energy and taking the time of many of the laryngologists of this country. Only three weeks subsequently the American

Medical Association met in Milwaukee, with a large attendance upon the Laryngological Section. In addition to these, the various State Medical Societies called out a considerable number of papers upon diseases of the throat and nose. Besides this, many of the laryngologists who contemplate going abroad have undertaken to prepare papers for the International Medical Congress which was to have met in Rome shortly after the close of this Congress.

When the American Laryngological Association held its first meeting in 1879 there were, all told, less than thirty men in the United States sufficiently interested in the subject to be counted laryngologists. But the ranks have been added to rapidly year by year, until now there are probably not less than four times that number who are well equipped; and in all of the cities and larger towns throughout the country are others more or less qualified who are doing considerable work in this special line, and it is probable that to-day 500 men could be found in the United States who might present something of interest to this body, though I have been able to discover only about 200 of them.

Nearly a year ago I opened correspondence with the physicians of Central and South America and of the West Indies, hoping to get them to join us in this Congress, but I regret to say that in only a few instances have I been able to obtain replies to my letters, and that only two or three of our colleagues in those countries have promised papers for this occasion. Considering the limited intercourse which has always existed between the United States and the Latin Americas, this is not a matter of surprise, but it is hoped that this Congress will be a beginning of closer alliance and personal friendships which will in coming years bring us often together, and build up a powerful International Congress in this western hemisphere.

The railroad already projected through Central America which will connect with various railroad systems in South America, and increased means of communication by sea will, it is believed, ere long open up to physicians of the United States many new and valuable resorts whose climatic influences may be made subservient to our patients in their search for health. When this has been brought about it is obvious that our acquaintance with the physicians in these southern climes will be of the greatest advantage to our patrons.

We welcome you, one and all, to our National Capital. We ask of each, your hearty coöperation in the work before us, and we believe the final results will justify the large amount of labor and anxiety which have been expended in this undertaking.

ADDRESS OF THE EXECUTIVE PRESIDENT. SECTION ON GENERAL SURGERY.

BY JOHN B. HAMILTON, M.D., LL.D.

CHICAGO.

Colleagues:—For the first time in the history of the American continent, the medical men of the Americas meet in convention, for the purposes of scientific advancement and the cultivation of closer professional relationship.

The country of WASHINGTON, the land of BOLIVAR, and the sunny islands of the southern seas, have sent their representatives to this capital of their

oldest republic, to exchange courtesies, and set forth a fair statement of their degree of enlightenment in the various branches of medical knowledge.

Our statesmen have long desired this close union between the American republics, and the medical profession, now as ever, stand ready as citizens to carry out their share of this patriotic duty. After our own civil war, the medical profession, through the American Medical Association, met in annual reunion at Atlanta; and it should always be a matter of professional pride that our own led the van in this march of professional and social reunion. Here again we are inaugurating the first of what we hope may be the beginning of a series of Pan-American professional congresses, each more interesting than its predecessor, and all serving to unite our glorious lands in common aims and mutual regards.

As the United States has had the honor of proposing the Congress, the burden of organization has fallen largely upon its representatives, and the overflowing program is to-day evidence of the faithfulness with which our President, our Secretary-General and their coadjutors have performed their task.

We welcome you, dear colleagues, to a rare treat in the republic of letters; our foremost medical men will address you, and the topics they bring for your consideration have living interest, for they are topics of to-day.

A glance at our program shows that our own Section, notwithstanding the subdivisions by which many branches of surgery have been organized into separate Sections, is ample to fully occupy the time set apart for our deliberations.

The rapid evolution of surgical knowledge is one of the wonders of this remarkable age, and surgeons may fairly claim that their own branch of medicine has kept equal pace with the stupendous advances made by the collateral sciences. A review of the surgical progress of the last decade, alone, constitutes one of the most brilliant pages of the history of medicine. And yet one must remember that all scientific progress is based on antecedent fundamental facts, discovered by slow, laborious and painful steps.

The labors of Darwin, Huxley, Herbert Spencer, Pasteur and Lister, in the last decade, have made possible the practical successes in the present decade.

There is at this time no diseased organ or tissue of the body that escapes the remedial scalpel, and an examination of the discussions of this time shows that the questions presented are rather those of method, than those of original discovery. We no longer question the propriety of surgical interference, in hitherto dark portions of human anatomy, but we are concerned in the technique of that interference; and to the improvement of surgical technique the ablest minds of the present decade have been directed.

The subject of surgical bacteriology, which includes the chemical study of microbic products, has still much to disclose, but we already base our practice on the immortal discovery of Pasteur. The success of modern surgical treatment, even with the imperfect knowledge of the bacteria that we now possess, is such that no surgeon thinks for a moment of comparing the results of any given operation with those obtained in the pre-microbic epoch. This comparison, however, only relates to the age of gunpowder, for history tells us with abundant detail, that the ancient treatment of wounds corresponded very closely with our own. The vulnerary com-

pounds of the ancients were largely composed of what we now know as antiseptics; the terebinthinate and metallic dressings of the Alexandrian period we can accept to-day as true anti-bacillary agents; and even the boiling oil and the red hot iron, we could now admit as forming an eschar, or impermeable wall against the entrance of microbes. It was aseptic surgery of which the ancients knew nothing. The empirical results of the boiling oil, of the actual cautery, were enough for the ancient masters; like the heroes of Balaklava:

"Theirs not to reason why;"

they only knew results were satisfactory, wounds healed quickly and without sepsis; what matter if the theory on which their treatment was based—that of arrest of hemorrhage—was faulty, the result satisfied them. Like the blind man of the New Testament the logic was simple: "Whereas I *was* blind, *now* I see;" therefore the touch was adequate. All medical science seems to have run in cycles, and there was less medical superstition in the Alexandrian period, than in medieval medicine—less in the Hindoocharaka than in the pages of Guy de Chauliac or Ambroise Paré. Bacteriology has added much to our knowledge of tuberculosis, and given more precision to its treatment, but that knowledge is still imperfect, and its treatment far from satisfactory. Much less has bacteriology added to our knowledge of the carcinoma, which still remain one of the mysteries of medicine. We have for years studied the varying departures of tissues from the normal to the abnormal type, and bacteriologists have in vain sought to connect the atypical structure of carcinoma with some bacterial development, but no Pasteur or Harvey has yet dawned upon our horizon to pick the lock of a mystery to which Heaven seems to have allowed our generation no key. Looking to the future we can not doubt that the solution of the formation of the carcinomata will yet be discovered, but it will necessarily be through the influence of some now totally unknown factor. The study of embryology and atavism seems at present the most probable avenue to the truth.

What may we hope for the future of surgery?

It seems likely at this day that improvements in technique will continue to occupy the surgical mind until some epoch-making discovery in physiology shall have been made. It is not likely that the present generation of surgeons will witness another discovery as far reaching as that of Pasteur. We must digest and fully assimilate the discoveries of the bacteriological epoch; that process will probably fully occupy our time and that of our immediate successors. It is true that we may have some help from advances in the collateral sciences; transillumination of the body for example, may be yet fully developed in our time, instruments of precision as aids to hearing and vision may greatly assist us in making our present knowledge useful, but the great outlets to human life such as carcinoma, in all probability will have their genesis understood only by the surgeons yet unborn. When that time shall come, carcinoma and tuberculosis will be classed among the preventable diseases. These two affections have cost more human lives annually than cholera or yellow fever, and yet no government has ever set on foot any systematic and regular inquiry into their causation or propagation. It is true that the study of cattle tuberculosis

has been the subject of much study by the Bureau of Animal Industry, but so far as the human race is concerned little has been done in the direction indicated.

Colleagues! I feel that I have too long detained you with these speculations, when we have before us a program so rich and so varied, but I can not refrain from expressing my heartfelt congratulations on the success of this meeting, my thanks for your generous response to the call for papers, and as an American surgeon to bid you welcome. Welcome, thrice welcome, foreign colleagues, to our hearts and homes. We pray you to kindly join us in warmest fraternal greetings to our European guests, and let us remember the saying of Livy that true friendships are immortal.

NECROLOGY.

Dr. Clinton Armstrong of Carrollton, Ill., died at Eureka Springs, Ark., August 23, aged 70. He was surgeon of the 61st Ill. Vols. and for many years a member of the Illinois State Medical Society and of this Association.

Dr. John F. Higgins of Port Jervis, N. Y., died at the German hospital in that city, Aug. 20, as the result of an accident received Aug. 16. He was a graduate of Bellevue Hospital Medical College class of 1879.

Dr. Augustus H. Salisbury of Minneapolis, died in that city, Aug. 26. He was a native of Canandaigua, N. Y., and 53 years of age. He was the first health commissioner of Minneapolis and had practiced there since 1874.

Dr. Edgar G. Young died Aug. 17 at his new home in San Diego, Cal. He had been ill with a complication of lung and heart troubles. He was 47 years of age and leaves a widow.

Dr. D. A. Pancake died at Columbus, O., Aug. 28. Dr. Pancake was on his way to Columbus, but was taken sick in Cincinnati.

Dr. Henry H. Darst of Toledo, O., died in that city Aug. 25, aged 72 years.

Dr. Woodville S. Bates of St. Louis, died at Badenweiler, Germany, August 2.

A Hospital with a Single Bed.—This caption is not intended to apply to the average sickroom, but rather to indicate the modest beginnings of a missionary plant in a benighted section of Asia, at the city of Patna. Dr. Grace Mackinnon, in January rented a little mudhouse on the bazaar, and thither sent a patient from the city dispensary whose treatment was impracticable at the patient's own home. Since that time one patient has succeeded another until a series of ten has been under treatment. Other patients take up a temporary abode in some house near the gates of the dispensary, in order to enable the lady physicians to economize their time and steps. "It is the day of small things, but we are very far from despising our hospital with its one bed; far from it; we take great pleasure in it, and we have come to know some of the patients really well by its means."

Blank applications for membership in the Association, at the JOURNAL office.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

NO. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., LOCK BOX 1274, PHILADELPHIA, PA.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 9, 1893.

THE PAN-AMERICAN MEDICAL CONGRESS.

We publish this week the address of President PEPPER, the address of Surgeon General STERNBERG on Military Surgery, the address of Professor WARREN, Executive President of the Section on Pedagogics; the address of Professor HUGHES, Executive President of the Section on Neurology, and the opening remarks of Professors INGALLS and HAMILLTON, Executive Presidents respectively of the Sections of Laryngology and General Surgery.

A careful perusal of these addresses will show that, with scarcely an exception, the authors have taken a broader view of the scope of the Congress than a mere professional one.

The Congress is looked upon as the initial step towards cementing the grand brotherhood of American States into commercial and professional union. Political union may not be desirable, but commercial and professional unity of action will develop the Americas as nothing else could develop them. The republican idea, too, will gain new strength throughout the world, as an indirect effect of these periodical exhibitions of power.

CHOLERA.

The latest advices from Europe show that there is not much change in the cholera situation in Russia, but that the previous ratio of increase is maintained.

In Hungary and Galicia the disease is increasing. It is admitted that in Hungary three hundred communes are infected. In Galicia fifteen districts have been invaded and the disease is still spreading.

On the 1st inst., in Obecoe, in Hungary, there was a cholera riot owing to the removal of the corpse of a cholera patient.

The ignorance and superstition of the people prove a serious obstacle in the way of the authorities in the enforcement of proper sanitary precautions, leading inevitably to the spread of the contagion. This

is to be observed in Persia as well as in Hungary. There is no increase in Vienna.

The disease has broken out among the Jeddah pilgrims on the island lying off the city of Mogador in Morocco, as anticipated. We have not yet reliable returns of the instances in which these returning pilgrims have developed the disease or the places to which they have carried it. It is evident, however, that it is no longer confined to the northern shores of the Mediterranean, but is spreading on the southern seacoast as well.

In Italy, Genoa has been reached. New cases have appeared in Alessandria, and several other new points have been reported, but the disease does not seem to be spreading to any great extent. The number of cases has been greater at Palermo than at any other point.

In France, deaths have occurred at Nantes, one of the victims being a physician who had treated cases in hospitals.

New points are constantly infected in Germany, Holland and Belgium, but the authorities are keeping the disease under control wherever it appears. Another death has taken place at Hull. The port of Grimsby in Lincolnshire, has been declared to be infected with cholera, and traffic between it and other British ports has been prohibited. What has become of their *no quarantine* system in England? During August eighty deaths occurred from what was called choleraic disease. It is now believed that many of these were due to cholera. Why was not the character of the disease discovered before? This was to be expected, inasmuch as emigrants from the continent pass through Grimsby in considerable numbers en route for the United States, by way of Liverpool. A number of cases have also been found in Jersey City, the origin of which has not yet been satisfactorily traced. Every effort is being made to prevent the spread of the disease from that point.

PHYSICIANS CAN HAVE BUT ONE SATISFACTION.

Physicians can have but one satisfaction of their bills. An important illustration of this principle, suggestive of a wide application for it, occurs in the case of *Woon v. Muxon*, decided by the Supreme Court of New York, July 8, 1893, (just reported, 24 N. Y. Supp. 286). Here a physician and health officer of a town attempted, by way of counter claim, in a suit brought against him, to collect the balance of his charge for attending a family through an epidemic after a portion of his bill had been allowed by the town. The court, however, said that the physician having presented his bill to the auditors of the town was evidence, as against him, that he was employed by the town to attend the family in question. The fact that the auditors allowed a portion of his charge was also evidence to show such employment.

They would have no right to make him a present or to make him any allowance on account of such services unless a legal charge against the town. The presentation, audit, and acceptance of what was allowed him, extinguished his claim. When he voluntarily presented his bill as a claim against the town, the audit of the town board was a legal adjudication of the amount due thereon. Moreover, if there were any liability on the part of the person whose family was attended, as well as the town, for such attendance, which the physician might have properly claimed, his presentation of a bill to the town, and acceptance of the amount at which it was audited, must have had the effect of also extinguishing the claim as against such person. Where a debt owed by two joint and several debtors, is satisfied by either, nothing remains for either to pay. If the debt is once satisfied, to allow recovery again, even if against another person, would be to allow a satisfaction twice upon one debt. So when the physician above mentioned presented his claim to the town auditors as against the town, and accepted the sum that they allowed thereon in payment, the transaction extinguished his claim against the head of the family attended, if any such claim ever existed.

THE NEW PHARMACOPEIA.

A new revision of the Pharmacopeia has just been placed upon our table. We will give it careful review as soon as practicable. At a hasty glance the publication shows that many changes have been made; a great many drugs have been dropped from the former list and many new preparations added. It has been revised with more care than any previous edition, and gives evidence of high scholarship and a thorough understanding of the necessities of the profession. The last revision of the Pharmacopeia prepared the way for the decimal system of weights and measures by providing that medicinal preparations should be composed of parts by weight. In this edition, the decimal or metric system is employed in the compounding of preparations throughout without qualification or translation. This change must be approved by all who appreciate simplicity in our system of weights and measures, and we predict that by the time the next revision shall take place the medical profession will have generally adopted the decimal form in prescription writing. The form is so easy and simple when compared with the complicated system of grains, scruples, drachms and ounces, as to make it a matter of wonder that the decimal system should have so much difficulty in the way of its adoption.

When it shall have become generally used it will be as impossible to return to the present English system as it would be for our bankers and business men,

generally, to return to the English monetary system and account for financial transactions in pounds, shillings and pence. To be sure, there will be some difficulty in the minds of those long accustomed to a certain method, whatever that method may have been, but the medical profession, ever progressive, will soon adapt itself to the changes made necessary by the advances of science. We sincerely hope that no misguided person will publish sets of complicated rules for the conversion of the English system into metric doses, for the reason that it is not rules for conversion that are now needed. The prescriber should learn the dose of his preparation or drug according to the decimal doses; then when a single dose shall have been learned it is only necessary to multiply the units of that dose by the number of doses he wishes to administer. Complicated rules for conversion have long stood in the way of the practical adoption of the decimal system. Let us have dose tables in convenient form for immediate reference, that can be carried as a memorandum in the pocket and a moment's reference, then, will refresh the mind as to the exact dose and there need be no danger of making mistakes.

The American Metrical Bureau of Boston long ago published dose tables, with statements according with the foregoing remarks, but as time has gone on they have passed out of the minds of many and it is again necessary to bring them into view. The American medical gentlemen of the future will be astonished to find that more than a quarter of a century was required to effect the change from an arbitrary to a decimal system of doses after a hundred years of trial of the same system in the coinage of the country.

In our review columns we will again refer to some of the more prominent features of the Pharmacopeia.

SOCIETY NEWS.

DOMESTIC CORRESPONDENCE.

Staff Correspondence of The Journal.

JOURNAL TRAIN, C. & O. R. R., Sept. 3, 1893.

The JOURNAL train left Central depot on time at 8:30 and traveled through the country without incident until nearing Indianapolis, where it was delayed an hour and a half by a wrecked freight train. The train service was excellent and the doctors, although delayed, preserved their equanimity and arrived in Cincinnati in good order. The St. Louis contingent were delayed for some reason or other and did not unite with the train at Indianapolis as was expected. The following named gentlemen among others were on the train:

Mr. Ernest Hart, editor *British Medical Journal*, and Mrs. Hart; Dr. Daniel R. Brower, Chicago; Dr. J. R. Wolfe, Prof. Ophthal., Glasgow; Dr. J. W. McLaughlin, Dr. E. H. Root,

Dr. A. M. Bromworth, Dr. C. M. Hobby, Iowa City; Dr. Bayard Holmes, Dr. E. F. Ingals, Dr. R. C. Corr, Carlinville, Ill.; Dr. S. H. Stevenson, Dr. S. S. Bishop and Mrs. Bishop, Dr. Geo. H. Cleveland, Dr. F. C. Green, Dr. W. Y. Dougall, Joliet, Ill.; Dr. P. C. Coleman, Colorado, Texas; Dr. James M. Craighill, Baltimore; W. J. Williams, Odell, Ia.; J. W. C. Love, City of Mexico; the editor of the *JOURNAL* and Mrs. Hamilton. Mrs. Holland, the stenographer of the Chicago Medical Society, was also of the party.

At Indianapolis the party were called upon by Dr. Woodburn and others who wore badges showing that they were on the Reception committee of the Grand Army of the Republic, which meets in Indianapolis this week. The city of Indianapolis was gaily decorated with flags, and presented the appearance of a place about to have a great fair or public entertainment. We were told that 200,000 strangers were already in Indianapolis attending the Grand Army encampment.

Prof. Weismann's Theories.

A late thoughtful editorial in *THE JOURNAL* on "Studies of Heredity," commenting on Dr. Weismann's published essays on this subject, seems to endorse the German professor's doctrines as the latest accepted conclusions of science. No mention is made of the widespread criticisms which Weismann's theories have called forth, the most notable of which perhaps are from the pen of Herbert Spencer in the *Contemporary Review*. After expressing surprise at the wide acceptance of Prof. Weismann's theories by the biological world, Mr. Spencer proceeds to show that the most fundamental proposition in his "Essays"—that on which the whole superstructure of his biological arguments rest—is untenable.

Prof. Weismann's primary contention is that animal organisms consist essentially of two kinds of ultimate cells—the somatic or nutritive cells and the reproductive germ cells; that the former are perishable but that the latter are immortal; that is, that in the propagation of the species from generation to generation, the reproductive cell is transmitted as such, retaining its distinctive nature in contrast with the somatic cell which varies according to the nutritive functions performed by it, and finally perishes when nutrition ceases. In a summary way and with masterly skill, Mr. Spencer entirely demolishes this theory. He proves conclusively that in important divisions of the animal kingdom, the alleged reproductive cell is wholly dispensed with for many generations together. Therefore, the transmission of hereditary qualities can not reside in the substance of these germ cells. Even in vertebrates, Weismann admits that the distinction between the two kinds of cells is not evident until the embryo is completely formed. Only nutritive cells during this period can be shown to exist. But the impress of heredity marks this period as plainly as any later stage in the development of the organism. Hence, Weismann's assumption becomes pure supposition.

The further assumption that acquired traits in the parent can not be transmitted to the offspring because the germ plasma from generation to generation is continuous and immortal and therefore unvarying, is shown to be equally without foundation. The great English scientist in his discussion appeals constantly to facts. And it is by an array of incontrovertible facts that the German professor's theories are upset. He shows conclusively that acquired traits are transmitted, not only in the human species but also in the animal kingdom generally. The evidence presented on this point by Mr. Spencer would seem to be sufficient to set-

tle finally the vexed question of the transmissibility of acquired traits.

Aside from the interest attaching to the consideration of the problems presented in Dr. Weismann's book, the discussion is extremely interesting as illustrating the different methods by which the ultimate truth is reached through scientific research. Theories are as necessary in scientific investigations as facts. But the observed facts must support the theories. Dr. Weismann insisted upon this and, like Mr. Spencer, makes his appeal also to the facts. But when the facts are observed through the false medium of an erroneous theory, the facts themselves become distorted, and it is not every mind that can allow for the aberration. Here is Prof. Weismann's weak point. In his eagerness to sustain his contention, he permits himself to bridge over great gaps in his theories by supplying suppositions. And through these gaps Mr. Spencer comes up with a phalanx of adverse facts which completely demolish the theories.

Prof. Weismann's books on this subject represent, no doubt, the work of a lifetime. His writings bear the impress of great erudition, and of elaborate, painstaking workmanship. Upon the soundness of the biological views advanced and advocated, the author has evidently staked his reputation as a man of science. To see these works rudely assailed and their fundamental doctrines discredited seems pitiless and unkind. But it is thus that science makes advances. No fabric that rests upon false foundations, however famous the architect or imposing the structure, may rest secure from her attacks. And in the onslaught against all forms of erroneous belief, the one trait of judicial mindedness counts for more in the outcome than all the other qualifications besides of the investigator. Here is where Mr. Spencer stands preëminent, and his methods are models for study for any who may have the inclination or the aptitude for scientific investigation.

JAMES L. TAYLOR, M.D.

The Pensacola Board of Health.

PENSACOLA, FLA., Aug. 26th, 1893.

To the Editor—Sir:—As requested, the following statement of the reported outbreak of yellow fever in the city of Pensacola, Florida, is made for the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*:

On August 9th, the attending physician reported that Rev. F. C. Waite and Ellen Wood had died that morning of yellow fever. This report came to the Board of Health without any previous notice of even a suspicion of the existence of yellow fever in the city. Steps were immediately taken to isolate and guard the premises where those deaths had occurred, both of which are in the northern part of the city, and separated about five blocks. An autopsy was held during the afternoon of the same day, and the physicians performing the same, decided that both deaths had been caused by yellow fever.

Upon this, the county health authorities gave notice by wire to the State and the United States health authorities, and also to the Health Boards of adjacent States. Joseph Y. Porter, M.D., State Health Officer of Florida, arrived on the night of the 10th and next morning assumed official charge of the investigation of the decision of the reporting physicians, and the probable origin of the contagion. Under the direction of the State Health Officer, acting through the County Board of Health, a house-to-house inspection was at once begun and vigorously prosecuted, and in the meantime measures were taken to trace every rumored suggestion as to how yellow fever might have reached this city. P. A. Surgeon, G. M. Magruder of the Marine Hospital Service, arrived here on the evening of the 11th, and

Surgeon H. R. Carter of the Marine Hospital Service arrived on the morning of the 12th. These gentlemen entered at once into hearty coöperation with State Health Officer, Dr. Joseph Y. Porter, in carrying out his plan of investigation.

On Monday, Aug. 14th, the following official bulletin was published by the State Health Officer:

OFFICE OF THE STATE HEALTH OFFICER OF FLORIDA.

PENSACOLA, FLA., Aug. 14th, 1893.

To the Public:—The State Health Officer of Florida announces that an investigation in the cause of death of Rev. F. C. Waite and Ellen Wood, who were reported to have died of yellow fever in the city of Pensacola on the 9th day of August, has been thoroughly and impartially made, in which he has been ably assisted by Surgeons H. R. Carter and G. M. Magruder of United States Marine Hospital Service.

These gentlemen agree with the conclusions herein expressed.

These cases were not seen either in life or after death, and therefore the opinions hereinafter noted are based on:

The clinical history of the cases.

The record of autopsies, and the statements of the relatives, nurses and friends of the decedents who were in attendance during their late illness.

There is nothing in the clinical history of the autopsy of the Rev. Waite to justify a diagnosis of yellow fever. On the contrary he seems to have died from acute gastro-enteritis with marked abdominal symptoms.

In the case of the child, Ellen Wood, the opinion is given, that while the record of the case clinically and from the autopsy, does not give a clear history of yellow fever, yet it contained sufficient evidence to justify the statement that the case was "suspicious," and demands precautionary surveillance and disinfection of the dwelling and its contents, together with the premises.

At this present time there have been no other cases of yellow fever nor suspicious cases reported. A house-to-house inspection, which has been made within the last three days and is now completed, discovers no sickness of a suspicious nature among the residents of the city.

[Signed] JOSEPH Y. PORTER,
State Health Officer.

Surgeon R. D. Murray, the distinguished yellow fever expert of the Marine Hospital Service, arrived on the night of the 14th and after a thorough examination of the whole matter, fully concurred in the opinion of the State Health Officer and the concurring surgeons, as expressed in the bulletin of the 14th. And it is proper to add that the statements therein made were in full accord with the opinion of the local health authorities.

As further history of the reported outbreak and investigation, an extract is here quoted from an official announcement by the State Health Officer on Aug. 18th:

OFFICE OF THE STATE HEALTH OFFICER OF FLORIDA.

PENSACOLA, FLA., Aug. 18th, 1893.

To the Public:—The State Health Officer expresses the belief that the fears and apprehensions of the health of Pensacola, which for the past week have agitated the public, involving the interdiction of travel and the consequent embarrassment to commerce, should now cease.

Of the reported deaths on the 9th inst. a thorough and impartial investigation into the history of the cases confirms the opinion heretofore announced that the Rev. Waite did not die from yellow fever, and that the death of the child, Ellen Wood, from the history, was of such a doubtful nature as to only warrant the disinfection of the dwelling as a sanitary measure, which precaution the public was entitled to receive by reason of this element of doubt. This has been done under the direct supervision of the State and United States government officers.

Since this investigation was begun and during the entire progress, the State Health Officer has been cognizant of all diseases and ailments which have existed or occurred in Pensacola, and is able to aver that no cases have occurred of a quarantinable contagious nature. This fact, coupled with the long period of active and retrospective observation, warrants the statement that there are no hidden causes which may produce it.

A notable fact in connection with these cases is that during their occurrence no precautions were taken to prevent any possible infection from them, and free and unrestricted communication was had with each, notwithstanding which, there have been no developments of a suspicious nature among the non-immune so exposed; and further, that the meteorological conditions during that period were peculiarly inductive of yellow fever, had the germs of the disease been introduced in the place.

Under orders from the Department, Surgeon Carter left Pensacola for Brunswick, Ga., on the 14th, but the investigation into the sanitary condition of the city was continued until 6 p. m. on the 19th, and the result is set forth in the following bulletin issued at that date:

THE CITY'S HEALTH.

Now that the yellow fever scare is a thing of the past in Pensacola, those who fled from the city when the alarm was given should be coming home to take part in restoring business to its accustomed channels. A great many have already returned, and those who yet remain away need feel no hesitation in coming back. The city was never more healthy, and the following, which is printed as a part of the history of the scare, should assure every one who has a lingering doubt of the real condition of affairs here:

PENSACOLA, FLA., Aug. 18, 1893.

We, the undersigned representatives of the health departments of the State of Florida, the United States of America and the City of Pensacola, do hereby announce that after a thorough and careful inspection of this city, we have failed to find the existence of any infectious disease whatever.

[Signed] Respectfully, JOSEPH Y. PORTER,
State Health Officer.

R. D. MURRAY,
Surgeon U. S. Marine Hospital Service,
G. M. MAGRUDER,
P. A. Surgeon U. S. Marine Hospital Service.

ROBERT W. HARGIS,
Pres. Escambia County Board of Health.
Very truly yours,
ROBERT W. HARGIS,
Pres. Escambia Board of Health.

Wants Cerebrine.

To the Editor—Dear Sir:—Will you kindly insert the communication herewith transmitted, in your correspondence column, and oblige. Very truly yours,

G. ARCHIE STOCKWELL.

650 Congress street, E. Detroit, Mich.

\$5.00 Reward.—The undersigned will pay \$5.00 each for a few bottles of cerebrine (Hammond) of the lot issued by the Columbian Chemical Co. in May, 1893. This cerebrine was devoid of sophistication by nitroglycerin, and moreover did not have the label of the Columbian Chemical Co., cross-stamped by fac simile in red of Hammond's signature.

Address DR. ARCHIE STOCKWELL.

650 Congress street, E. Detroit, Mich.

BOOK NOTICES.

A Manual of Diseases of the Ear. By GEORGE P. FIELD, M.R.C.S., Aural Surgeon and Lecturer on Aural Surgery, St. Mary's Hospital, Medical School, London. In one octavo volume of 391 pages, with seventy-three engravings and twenty-one colored plates. Cloth \$3.75. Philadelphia: Lea Brothers & Co., 1893.

The American publishers of the fourth edition of Field's work on "Diseases of the Ear" have furnished to American readers an excellent work on otology.

The first thirty-two pages are devoted to the anatomy of the ear illustrated by twenty-seven woodcuts.

Nine pages are devoted to its physiology, with one illustration giving diagrammatic view of the organ of hearing.

Twelve pages, with six illustrations, are devoted to the methods of examination of the ear. The next fourteen chapters deal with diseases of the ear.

Chapter eighteen treats of deaf-mutism, its causes and statistics, as well as methods of instructing deaf mutes. The final chapter is on aids to hearing including ear trumpets, artificial membrane, audiphones and rodosteophones. The three chapters in which diseases of the auricle and external meatus are considered, give a full exposition of the diseases and accidents to that part of the ear, with which the general practitioner of medicine has more especially to deal, and will be of interest to them as well as to otologists.

The next seven chapters are devoted to the membrana tympani and the middle ear where the interest of otologists largely centers, since most of the affections and injuries of these parts are most dangerous to hearing, and not infrequently to the life of the patient.

Chapter fifteen deals with the most difficult part of the hearing apparatus—the internal ear or perceptive apparatus.

Diagnoses of the affections and injuries of the external ear, and their treatment, are well presented by the author. Naturally they are the least difficult of recognition, and the methods of treating them as detailed by the author will interest all physicians who are called upon to treat those diseases or injuries.

The variety of the conditions of the middle ear resulting in impairment of its function, whether from inflammation simple or suppurative, acute or chronic, or from mechanical violence, is well presented by the author. Their diagnosis is facilitated by the manner in which the subject is treated in the text and illustrations.

The therapeutics and surgery of the part will be recognized as presenting the advances made in this subject in the last quarter of a century.

The author's experience coincides with that of others, that of the many devices designed to aid those with impaired hearing, only ear trumpets and conversation tubes have given any great amount of assistance, except in a limited number of instances.

The illustrations of the work are fair, but most of the chromo-lithographs can scarcely be considered more successful than such efforts in the field of surgery usually are, when too often they are only misleading. Figure 53 is given as "method of passing the Eustachian catheter," but it is so evidently a mistake that no one would be likely to be led to believe otherwise.

The work as a whole will be welcomed by the medical public.

MISCELLANY.

Prof. Joseph R. Wilson of Philadelphia, recently delivered a lecture in the Mining Building at the World's Fair on "The Detection of the Presence and the Percentage of Explosive Gases in Coal Mines, and how to prevent Explosions and Loss of Life."

The apparatus by which this is accomplished consists of two pumps, one of which takes in pure gas and the other pure air as a basis of measurement. The cylinder is arranged so that any desired percentage of gas in conjunction with air can be produced, while the component parts always equal 100. The product of the two cylinders is pumped into the igniting chamber, which has an aperture in front of a gas jet. Should the mixture be ignitable, ignition will immediately take place and the expansion caused by the heat propels a loose piston head at the end of the chamber against a gong, which is caused to sound.

As can readily be seen, the percentage of explosive gas is accurately obtained.

By means of the comparative turpidity of CO₂ in lime water, this apparatus ascertains the percentage of CO in the exhalation of the breath and thereby determines the

condition of the lung tissue. In the treatment of consumptives this discovery is of great benefit to the medical profession, as an opportunity is given to watch the daily progress of the disease.

Emin Pasha (Dr. Schnitzer).—Dr. Junker, the African explorer, recently passed through New York. When asked what he thought of the reports of the death of Emin Pasha, stated that he discredited such reports, and that his belief was that Emin was securely established at or near the Albert Nyanza. The latest report that has come down to the coast from Lake Tanganyika asserts that Emin had been slain and eaten at an Arab station about one hundred miles west of the Albert Lake. An English missionary, named Swann, writing in April last, states that the event fatal to Emin took place in October, 1892. This news comes through several independent, though Arab, sources.

There is nothing hazy about the Surgeon General of Siam.—Dr. T. H. Hayes, a graduate of the Maryland University, and a few years ago a struggling drug clerk, is now, although still a young man, surgeon general of the Siamese army and physician to the household of the king. He is also at the head of large educational institutions, which he has modeled after prominent schools of learning in Baltimore, is in charge of all the hospitals, and, moreover, frequently preaches to the natives and foreign residents, being an accredited minister of the Presbyterian church. He receives from the king a salary of seven thousand dollars a year and perquisites.—*La Salle Tribune*.

Prosecuted on account of a Postal Card.—Dr. James E. Reeves' formerly of Wheeling, now of Chattanooga has been sued for damages on account of the following postal card, writ, ten to Dr. Mettner of Cincinnati:

CHATTANOOGA, Aug. 14, 1893.

My Dear Doctor:

I have sent your name in Amick's pamphlet. Please give me the outcome of your experience with the so-called "chemical treatment" for consumption. The enterprising managers have within the last month made Chattanooga a sort of head-center for sending out in the secular press wonderful cures which are pure fabrications. Not a particle of proof can be furnished that a case of tubercular consumption has been cured, or benefited by the so-called treatment. Has Cincinnati sold out and moved to Chattanooga? Verily, it seems so. Speak your mind fully to me.

Sincerely yours,

JAMES E. REEVES.

Dr. Reeves is full of fight, and says he will expose the whole thing in court next October with great pleasure.

Board of Health Resign.—Four of six members of the Columbus Georgia Board of Health including the President, Dr. Ticknor, resigned because the city council refused to pass an ordinance of quarantine against Brunswick.

Dr. Frank E. Waxham of Chicago, has been elected to the chair of Laryngology and Clinical Medicine in the Gross Medical College of Denver.

The Protestant Hospital Association of Duluth, Minn., capital \$50,000 has been incorporated.

LETTERS RECEIVED.

REPEATED EXTRA-UTERINE PREGNANCY WITH THE REPORT OF A CASE.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY GEORGE I. McKELWAY, M.D.

PHILADELPHIA

On the 14th of February, 1891, Mrs. M., the wife of a lawyer, consulted me, giving me the following history:

She was 30 years old, had been married the previous September, had been perfectly well and had believed herself two months pregnant, when, on the 25th of January, 1891, while staying at Atlantic City, she had a profuse hemorrhage from her uterus. A physician was called who, from her statement of probable pregnancy and hemorrhage alone, diagnosed an abortion. The patient did not remember having passed any mass, or having at that time had any severe pain or colic.

This physician saw her only once more in the ten days that followed. On the tenth day she sat up and for one week thereafter the hemorrhage continued. She said that the physician made no examination at any time and gave her no treatment except to order her to keep her bed for ten days. When she called on me she was still losing some blood, not amounting to hemorrhage and as her trunks were packed to return to Philadelphia, where she expected to come within three days, I made no examination supposing the condition simply an incomplete abortion, but told her to complete her preparations for her return home, where I would see her and treat her as the case required. I expected to empty the uterus.

She returned to Atlantic City. Two days later, while still absent, she was suddenly seized with the most intense pain in the lower abdomen, fell to the floor and fainted. Dr. E. A. Reiley, living near by, (who had not seen her before) was sent for and had charge of her until the third of May, when she was able to be moved in a rolling chair to the train, was brought to Philadelphia, and came under my care. Dr. Reiley courteously furnishes the following history:

"Your letter asking for information concerning the case of Mrs. M. is at hand. I am away from home and cannot give dates with accuracy, not having access to my books, notes, etc.

"Some time in February of 1891, I first saw the patient at Atlantic City. I was called hurriedly, and on arriving at the house, found her on the floor where she had suddenly fallen while exerting herself in arranging to move to her home in Philadelphia. She was lying on her back, with the knees drawn up, and complained of intense pain in the lower part of the abdomen.

"The lips and face generally were white, ashy and drawn, the nose presenting a pinched appearance and the whole look of the woman was as that of one dying. She was bathed in a cold perspiration and had no radial pulse, but

was perfectly conscious and the pain seemed to be agonizing. As soon as possible after starting the use of the proper remedies, I attempted to make a vaginal examination, principally with the idea of finding signs of a miscarriage, or of a pregnancy. The os was closed and small, hard and resisting as in health, and there were no signs of hemorrhage flowing externally. On account of the great pain it occasioned I did not persist further in the examination at that time. In about an hour the radial pulse became perceptible. She was removed to a bed and in a few hours was apparently out of immediate danger. The pain persisted with diminished intensity for a week or ten days, and it was fully that time before a satisfactory examination could be made as I did not deem it necessary to use ether. During this time there was a slight yellowish discharge per vaginam. Upon examination I found a slightly fluctuating mass on the right side of, and in front of the fundus of the uterus. I should judge it to have been about the size of a small orange. From that time on it decreased in size and Mrs. M., though subject to some pain and soreness at times, made a continuous, though slow recovery.

"On the 14th of March I was taken ill myself and Dr. Kaemmerer took charge of the case for me but its slow progress was, I believe, without incident. I think she said at the time of the accident that she had not menstruated for two periods, but my memory is not clear as to what she told me about the time.

"I am sure the effusion was on the right side, although at this distance of time, with a long and severe illness of my own between, my 'quite sure' may possibly be wrong; but I think not as my memory of events connected with the case which came under my personal observation is very clear. I think I have stated everything that can bear on the case.

"On her return I made a careful examination and found just the condition that Dr. Reiley described. The uterus was normal in size and position and quite freely movable. There was no uterine hemorrhage and the right side presented a mass, at this time about as large as a lemon. This, from the history, was evidently being absorbed, and she seemed perfectly well, excepting anemia, so I did nothing more than to advise against over-exertion, give iron, etc., and look after her general health. In July there was no longer any tumor to be found. She was then seemingly in perfect health and I did not see her for five months.

"On the 2d of December, 1891, I received an urgent call to see her as she had suddenly been taken violently ill. I saw her at 5 p.m. I found her in bed propped up by pillows, face pinched and drawn, body wet with cold perspiration, and absolutely blanched by what proved to be an internal hemorrhage, radial pulse imperceptible, heart beating 168 times in a minute, respiration sighing; semi-conscious, and suffering excruciating pain in the lower part of her abdomen. The story was that her last menstruation had occurred seven weeks before and that she had supposed herself pregnant. The night before at 3 a.m. she had been awakened from sleep by violent pain. She cried out, awaking her husband; immediately lost consciousness and became very much blanched. Her husband called in the nearest physician, (a homeopath) who diagnosed a retroversion of the uterus as the cause of her condition. Assisted by her hus-

band he put the nearly dead woman in the knee-chest posture, stuffed her vagina full of cotton, and left her with the assurance that she would soon be better. She did not improve under this treatment and he was called again in an hour, removed the cotton and gave her a hypodermic injection of half a grain of morphine. These hypodermics were repeated at intervals until, when informed that I was coming, he left word that he had given her five of a half grain each.

I found the vagina bulging forward, the uterus pushed up against the pubic bone and somewhat enlarged, but presenting no evidence of hemorrhage. Her abdomen was very much distended and dull in both flanks. The head was lowered, the foot of the bed raised and hot water bottles placed about her. Hypodermic injections of digitalis and whisky, and rectal enemata of milk and whisky were given. A ruptured tubal pregnancy with very great hemorrhage was suspected and her husband informed that her only hope was through the prompt performance of an operation, to which he consented. Dr. William Goodell was asked to see her with me and assist in an operation if he deemed one advisable. On our return we found the patient almost unconscious. Dr. Goodell quickly examined her, agreed with me in my diagnosis and with very little preparation the operation was begun. Dr. Goodell kindly etherized her, but during the operation the ether was turned over to a nurse.

Her condition was so desperate that time was an element of the greatest importance and we were obliged to do some things which under other conditions would not have been done. Although instructions had been left on my first visit to provide an abundance of hot water, this, in their panic, had been neglected and we were obliged to use water from the spigots in the bathroom for our instruments and for irrigation. The cleansing of the abdomen also was very hurriedly and imperfectly done.

The abdomen was opened in the median line. There was no blood from the incision and the tissues were perfectly blanched. On nicking the peritoneum black blood spouted up through the opening. From the history of her former attack I believed the cause for trouble would be found on the left side. I passed two fingers through masses of clotted blood, and brought out, ligated and incised, the ovary and ruptured tube. The tube was enlarged to the size of a large lead pencil and ruptured in the middle third. The other ovary and tube were found adherent to the fundus of the uterus, and, whereas the ovary on the left side, on which this last rupture had occurred, was apparently healthy, this ovary and tube were disorganized; the ovary was enlarged and as soft as cheese, so that it was removed in fragments from its adhesions. After its removal the abdomen was freed from clots and fluid blood. A pint vegetable dish, the only receptacle at hand, was filled four times, and in addition a pint of fluid blood was removed by sponges. Her abdominal cavity was then irrigated with several pitcherfuls of water. (The water from the hot water spigot was too hot and had to be cooled from the cold water spigot.) The abdominal and peritoneal incision was closed without drainage and the patient removed to bed. Her condition was better than before the operation, though the radial pulse was still imperceptible and the thermometer

showed an axillary temperature of 96 degrees, but respirations were deeper and the pulse beat 140.

I remained all night and kept hot water bottles continuously about her, administered enemata of milk and whisky, and hypodermic injections of digitalis, whisky and strychnin, with I believe, one of atropin. For a few days the foot of the bed was kept elevated and she was denied a pillow. Rectal enemata of animal broths, beef juice, etc., with stimulants, were continued for three days. They were absorbed apparently without difficulty, due, I believe, to their frequent administration in small quantities. Thereafter she was fed as she could take food and the enemata were discontinued. She made an uneventful recovery and is now entirely well.

No products of conception were found, nor were they carefully looked for, as owing to the scarcity of vessels, the blood clots were emptied into the bathroom water closet close by as frequently as the vessels containing them were filled. The condition of the patient seemed so desperate and hopeless that there was neither time nor inclination for such a search.

The history undoubtedly indicates that she suffered a tubal pregnancy with rupture on the right side at Atlantic City in February, 1891, and in December, 1891, the left tube was ruptured because of a pregnancy in it. Each time she had symptoms of pregnancy—suppression of menstruation, morning nausea, pricking breasts, with symptoms and sequelæ of rupture. It is to be regretted that the fetus was not found and that the specimens were not examined microscopically.

Despite much speculation, the causes that lead to tubal pregnancy are not definitely or positively known. That *severe* salpingitis is not one, is evidenced by the fact that it leads to occlusion of the tube. Whether mild salpingitis, noticed upon microscopic examination of specimens from cases of tubal pregnancy is cause or consequence, remains undetermined. It seems fair to suppose—but it is only a supposition—that whatever the primary cause, the immediate causes of tubal pregnancy are an abnormal patency of the proximate end of the tube, or a stenosis of it elsewhere; with possibly a destruction of or loss of effective function of the ciliated epithelium lining it.

In view of this and other cases, which I shall subsequently recite, the question arises whether the existence of tubal pregnancy upon one side is an indication that the individual is prone to its occurrence upon the other, and whether this liability is so great, supposing operation necessary for an impregnated or ruptured tube, as to require the removal of the apparently sound tube and ovary.

My study of this and other cases leads me to the conclusion that both tubes and ovaries should invariably be removed in every case of ectopic gestation. The conditions which affect one cornu of the uterus, or one tube, are equally liable to affect the other. From the usual position of the uterus, with one cornu lower than the other, the most dependent tube may, from retention of decomposed discharges, be more prone to this accident; but any theory of immunity in one tube based upon a trifling difference of position will not justify leaving in the woman's pelvis that which may be an occasion of sudden and irremedial calamity to her.

The mere fact that women have suffered opera-

tion for a ruptured tube on one side, and have subsequently borne children without complication, is no argument in favor of such a procedure. It is fair to say that they have escaped a repetition of the calamity, *despite the fact* that all the elements for its occurrence were permitted to remain. The well-known case of Lawson Tait, quoted later, shows the danger of such a procedure, and the possibility that a normal pregnancy following an extra-uterine foetation is fairly to be considered more as an accidental occurrence than is a future pregnancy in the other tube and its possible fatal consequences.

Had the serious condition which occurred after the second rupture, followed the first one and operation been delayed, my patient would certainly have perished, and it is evident that she would have been spared the serious danger to her life through which she afterward passed, had she been subjected to operation at the time of the first rupture and the appendages of both sides removed.

That the danger of ectopic gestation in the second tube is not exaggerated is proven by the literature on the subject.

Parry (Extra-uterine Pregnancy—Its Causes, etc.) quotes cases as follows. He says:

"Campbell quotes from the *Journal de Médecine, Chirurgie, Pharmacie*, etc., 1785, the history of a woman whose eighteenth conception was erratic. She recovered and retained the child thirty-three years, and died at the age of 75 years. At her autopsy it was found that the abdomen contained an ovoid mass weighing five and a half pounds, composed of perfectly dry cartilaginous structures, inclosing a mature male fetus, with its funis and placenta. After the removal of this last, another body the size of a hen's egg, also cartilaginous, containing a fetus the size of one of two months, was found to the left side of the uterus."

This may have been a twin conception. Varnier and Mangin (Moreau, Des Grossesses Extra-utérines, 12mo., Paris, 1853, p. 115) in the *Journal de Médecine*, 1786, state that they made a postmortem examination of a woman who died aged 74 years, and they found what they believed to be a double ventral pregnancy.

M. Galiay (*Gazette Médicale de Paris*, July 29, 1737) has known a woman to conceive two extra-uterine children. In the interval between the two pregnancies, the product of the first was evacuated through the rectum, after which she enjoyed good health for five or six years, when she conceived again. This child also was located out of the womb, and like the first, was finally discharged through the bowel, after which the woman regained her health.

In 1850, Dr. F. Brown reported (*St. Louis Med. and Surg. Jour.*, May, 1850, p. 205) that he had the care of a woman who, after having aborted a number of times, finally carried a child to term, but it proved to be extra-uterine. Two years later she conceived again. At the end of the sixth month symptoms of labor came on, after which the cyst opened through the abdominal walls. The orifice was enlarged and the bones extracted.

In 1853, M. Oulmont had under his care, in the Hôpital de le Salpêtrière (Moreau, loc. citat., p. 110) a woman aged 31 years, who had never borne any children, and who died of rupture of the cyst when she was three months gone. At the autopsy

the product of the recent conception was found in the pavilion of the tube on the right side. A second tumor was found at the extremity of the left tube. It was smaller than the one on the right side, and contained a small anencephalous fetus, which, after an attentive examination, M. Oulmont concluded was the result of a conception some years before.

Parry also quotes in long detail a case from The Transactions of the London Obstetrical Society, 1863, an abstract of which is as follows: A woman died of rupture of a tubal gestation sac. There was a history of a previous probable ruptured tubal pregnancy four or five years before this later one. Dr. J. Tyler Smith and Dr. Braxton Hicks were deputed by the Society to examine the specimens and they reported: "That at some time previous the patient had conceived extra-uterine, and that the fetus died at about the second month, and that at some time after this pregnancy she again conceived extra-uterine and that the rupture of this second sac caused her death. This report was based on the condition of the tubes, uterus and ovaries and also upon the finding of two fetuses in conditions justifying these conclusions."

Dr. W. Gill Wylie (Trans. New York Obstetrical Society, Dec. 16, 1890) reports a right tubal pregnancy which occurred after the removal of the left tube and ovary. He is quoted as believing that the first ovary, tube and debris removed "may have been" a degenerated tubal pregnancy.

Lawson Tait, in the *British Medical Journal* of May 12, 1888, reports a case in which he removed a three months' fetus and ruptured right tube from a "belly full of blood clots and bloody serum." This on May 11, 1885. Eighteen months later the patient was delivered of a child at full term. Fifteen months after this delivery she became pregnant again and went to the fourth month. On a certain day at 1 o'clock p.m., she had the symptoms of rupture of a tubal pregnancy and died at 5 p.m. without operation. A postmortem disclosed a ruptured tubal pregnancy of the left side. In reference to this case, Tait makes the extraordinary statement: "In this case we have the almost incredibly strange instance of a woman suffering from tubal pregnancy twice, with the still stranger fact of her having a normal pregnancy between the two occurrences."

G. Earnest Hermann, in the *British Medical Journal* of 1888, Vol. 1, p. 1152, reports: "A Case of Extra-uterine Gestation cured by Abdominal Section two and a half hours after Rupture," as follows: He operated—removed a right ruptured tube and a four months' fetus. He says nothing of the left tube or of its condition, but the woman had been treated three years before by rest, etc., in the same hospital, for what had been diagnosed as a ruptured tubal pregnancy of the left side and had presented all the symptoms thereof—amenorrhœa, followed by a discharge of blood, etc., pain, shock, a tumor which subsided and disappeared. The uterus was enlarged to three and a quarter inches in depth and the temperature was 100° F. He says: "If the diagnosis of the first illness be correct the case is an instance of two successive extra-uterine pregnancies in the same individual—first in one tube, and then in the other. There may have an identical morbid condition of the right and left tubes which occasioned the failure of the ovum to reach the uterus."

Hermann also reports, in the *British Medical Journal*,

September 27, 1890: "A case in which second Tubal Pregnancy in one Patient was Diagnosed and Removed before Rupture," as follows:

"In January, 1887, right tube removed for a ruptured tubal pregnancy of that side. May 13, 1890, an unruptured tube containing a fetus was removed from the left side. He says in reference to this case, and probably with the thought of the case previously quoted in his mind: "Tubal pregnancy is so often bi-lateral that I think it probable that similar cases may hereafter be found to be commoner than appears to be at present supposed."

In the *British Medical Journal*, 1892, Vol. 2, p. 732, there is reported a case upon which Galabin operated and the specimen from which Bland Sutton examined. It was reported under the title: "A Case of Tubal Gestation in which both Tubes were Gravid—Operation and Recovery." Upon examination of the specimens Sutton writes: "In this case we have to do with pregnancy in each tube, but the pregnancy in the left tube is much more advanced than that in the right tube;" and, after quoting three other cases in which he believed that concurrent pregnancy in each tube existed, but in which the proof was not absolute, he again states: "In this case the existence of impregnated ovum in each tube is beyond all doubt."

Mackenrodt, in the *Zeitsch. für G. und G.* (Band 23, left 1) reports a case as follows: "In May, the patient had symptoms of tubal pregnancy and of rupture of the sac, but refused operation. In October, 1891, she again had same symptoms and operation revealed a left-sided gestation sac the size of a goose egg, and on the right side a sac, bound in by adhesions and inherent intestines, containing fetal bones."

Olshausen, (*Deutsch. Med. Woch.*, 1890, No. 9, p. 174) reports that on Nov. 1, 1888, he removed a living fetus from the right tube. One year later patient came again with all the symptoms of a ruptured tubal pregnancy. He now removed the left tube in which was decidua tissue.

Dr. Theodore Mayer of Copenhagen, is reported in the *Annals of Gynecology*, 1890, Vol. 3, p. 501, as having removed the tube and ovary of a ruptured tubal pregnancy from the left side on January 19, 1888. On September 6 the patient had a hemorrhage and fainted, and a soft mass was found on the right side the size of a large walnut. Two days after, patient fainted again and was in a collapsed condition for some time. On October 25 she had a hemorrhage of dark blood from her uterus, pain in the abdomen, vomiting, etc. On October 29 she "passed a membrane which had all the characteristics of a true decidua pregnancy." On November 13 "a big, soft swelling" was found to the right of and behind the uterus which grew harder and harder, and gradually disappeared.

In the *British Medical Journal* of June, 1892, Thomas Savage reports a case in which upon operation he found the right tube ruptured in the center and "an apple-pie form mole" escaped; on the left side, a tumor—"a black clot as large as the closed fist" was found adherent to omentum and intestines. The ampulla on that side was found dilated.

Bon-leau (*Lech. d'Obstet. et Gyn.*, May, 1892) gives the history of a case in which seven weeks after operation for ruptured tubal pregnancy, of which no particulars are given, operation for the same condi-

tion was again demanded. He states that microscopic examination of the specimens from both sides prove both to be tubal pregnancies.

Kletzsch, in the *American Journal of Obstetrics* of May, 1888, p. 520, details the case of a woman from whom Dr. Thomas removed an extra-uterine pregnancy (side not stated) in June, 1884, and who, in October, 1887, after cessation of previously regular menstruation for two months, had then and thereafter all the symptoms of ruptured tubal pregnancy; but who slowly recovered without operation. He states that Dr. H. C. Coe concurred in the diagnosis.

Albert Peuch (*Gaz. Obstet.*, Paris, 1879) reports two cases as follows:

Case 1.—A woman aged 30, having had seven labors, the last resulting in twins, became pregnant for the eighth time. At term she became ill and the movements of the fetus ceased. On recovery her menses were re-established and she finally became pregnant for the ninth time. The ninth pregnancy progressed to the eighth month when she developed an abscess in the abdominal wall, and was at the point of perishing. The abscess opened and a piece of bone was discharged. She applied to a surgeon for relief. He introduced a stylet into the cavity of the abscess and enlarged the opening with knife and forceps, removing a fetus, bone by bone. A tumor, referred to the left side, which was the product of her last pregnancy, was allowed to remain, owing to her feebleness during operation. Subsequently gastrotomy was performed and the product of her remaining pregnancy was removed, member by member. Contrary to all hope the patient recovered.

Case 2.—A domestic. Died twenty-four hours after a rupture of a tubal pregnancy, apparently four or five months advanced. At the autopsy all the organs were found normal except the uterus and its adnexa. The uterus measured four inches in length. The right ovary and tube were distended into a sac having a globular form and a diameter of three and a half inches. It contained a fetus at about the third month. Upon the side of the sac was a solid, irregular tumor the size of a nut, hanging by its membranous adhesion, like a polyp. Upon examination it was found to contain an embryo enveloped in the membranes proper. Six months before her death she had had intercourse a number of times with the man who had impregnated her the last time.

Bröse (*Zeitschrift für Geburtshilfe und Gynäkologie*, 17, '89, p. 335) demonstrated a tubal pregnancy on the left side with hemato-salpinx of the right tube, which he had removed by laparotomy. Patient was a 2-para. Three months after the cessation of her menses the decidua came away, preceded by hemorrhage on the day before. At the laparotomy a right-sided hemato-salpinx was found with brown fluid blood in the peritoneal cavity. The left-sided tubal pregnancy was not ruptured.

Veit (*Zeitschrift für Geburtshilfe und Gynäkologie*, Vol. 17, p. 335) exhibited a tube filled with blood coagula which he found by microscopical examination to have been the result of pregnancy. The tube he had removed by laparotomy from a patient upon whom he operated for a similar condition on the other side. He reported also two other cases in which he had operated and removed tubal pregnancies, and in each of which all the symptoms had returned at a later period, but the patients recovered without operation. Questioned as to the possibility of making a diagnosis, Veit replied that the menses were absent, the patients came under observation suffering severe pain; after entrance to the hospital they had slight hemorrhage, in which no parts of the ovum could be recognized. There was a hard tumor of the tube from which the pain radiated.

Von Heukelom (*Centralblatt für Gynäkologie*, No. 3,

1887) refers to a case, described by Dr. Nölampin (*Nordl. Tijdschr. v. Geneeskunde*, 1885), dying of internal hemorrhage from the rupture of a tubal pregnancy. On autopsy the uterus was found reaching to the upper level of the symphysis, with thickened walls of soft consistency. The right tube about four centimeters from the uterus, has been distended, forming a cyst about the size of a walnut, which had ruptured. In Douglas' pouch was found a large mass of soft fresh coagula containing an embryo, upon which the eyes and ears could be recognized. Upon the left tube about four centimeters from the uterus was a fissure two centimeters long. At this position were found a number of flakes of connective tissue and membranes resembling torn tissue. Upon the posterior surface of the ligamentum latum were seen a number of flakes of circumscribed yellowish brown coagula lying in little pockets. The left ovary contained the remainder of an old corpus luteum. The right ovary showed on section a corpus luteum the size of an almond. He believed that very probably three or four months previously conception had taken place and the ovula had found attachment in the left tube, developed and, six or eight weeks before the woman's death, the sac had burst, giving rise to a small hemorrhage which had soon become encapsulated. This was explained by the yellowish brown coagula and the fissure in the left tube. Soon after, an impregnated ovule had become attached in the right tube, developed and ruptured; causing the woman's death.

Lopes (*Revista de Medicina y Cirurgia Practica*, 1880) refers to a case described by Silva. The woman died suddenly with signs of an acute inflammation. On autopsy a tumor was found containing five liters of sero-sanguineous fluid, which was demonstrated to contain the products of conception. The placenta was situated in the right iliac fossa. In the superior part of the epigastrium another sac was found from which a female fetus was removed.

Dr. John W. Taylor, in the *British Gynecological Journal*, August, 1892, p. 168, reports a case as follows. He says:

"On December 22, 1889, after nearly six months' amenorrhea, during which she believed pregnancy had begun, the patient was attacked with symptoms of peritonitis. Coincident with this, a tumor—evidently a hematocele—developed on the left side of the uterus. I diagnosed the condition as probably due to the rupture of a tubal pregnancy, but the hemorrhage was not severe and was evidently circumscribed by local inflammatory action. In twelve hours all the more acute symptoms had subsided. When I next saw the patient a well developed hematocele of considerable size remained in the pelvis. The patient was kept in bed six weeks, by which time the hematocele had become absorbed and the parts, on examination, had returned to a fairly normal standard."

Two years after, Dr. Taylor operated on this same patient for a ruptured tubal pregnancy and removed, from an abdomen full of blood, the left tube and gestation sac. He found a recent rupture (he doesn't say exactly where) in the tube, but states that near the end of the tube there was an old rupture which he believes to have been occasioned by the previous attack. He states that the other ovary and tube were apparently healthy and normal and he left them in.

This case is an exceedingly rare one as his belief is that this woman suffered two ruptured tubal pregnancies in the same tube. In the fact that the same tube was involved each time it differs from the other cases I have quoted.

Frommel, in *Monat. H. b.*, 1890, No. 23, p. 494, describes a case as follows:

"In 1883 he operated upon a woman, 33 years old, eight days after the rupture of a tubal pregnancy and extracted the fetus, etc. This pregnancy was in the right tube. Four years after, in May, 1887, the patient's menses ceased for eight weeks; she was suddenly seized with pain in her abdomen on the left side, with vomiting; she fell in the street, became suddenly pale and no pulse was to be found. The next day she expelled membranes which a microscopic examination showed to be decidua."

"On vaginal examination a tumor elastic, filling the pelvis and pushing the uterus forward and upward, was found. The patient recovered from this acute attack and four weeks after again had all the symptoms of internal hemorrhage. The tumor increased in size and there remained thereafter a hematocele. This slowly diminished and the patient made a slow recovery."

Dr. W. A. N. Dorland of this city has kindly furnished me particulars of the following case, which was operated on successively by Dr. B. F. Baer and Dr. Dorland:

"On the 11th of October, 1890, E. L. called, at the dispensary of the Polyclinic hospital. She was then 28 years old, had had four children—the eldest six years and the youngest fifteen months old. She said that she had missed her menses for three weeks and believed herself pregnant, but that after two weeks her menses came on although not so freely as formerly and the discharge was much lighter in color. When menses returned they were associated with cramp-like pains—"a bearing down not unlike labor pains." She was having repeated rigors followed by fever; was anemic and very much prostrated and the abdomen was quite enlarged. The cervix was found on the floor of the pelvis, the os was patulous, and the body of the uterus was enlarged to the size of the second month of gestation. To the left was found a circumscribed mass, apparently attached to the uterus, fluctuating, about the size of an orange, and tender on pressure. Operation was done by Prof. Baer on the 20th of October, 1890 and a ruptured tube of that side with fetus in situ, blood clot, etc., found and removed. She made a good recovery."

"On the 19th of July, 1892, the patient returned saying that she had the same symptoms as before, excepting that this time the right side seemed involved, and she thought she was pregnant again in the same way. Examination showed a slight increase in the size of the uterus and a small tender mass on the right side. Dr. Dorland says: On August 10 I was sent for at 1:30 p.m. Found her pale and anxious, she had had a severe attack of pain on the night of the 6th of August; on the 7th, a discharge of blood from the womb; on the 8th five fainting spells. Examination showed womb considerably enlarged and tumor to the right much increased in size and perceptible through abdominal wall; a boggy mass in Douglas' pouch; operation same day; tubal pregnancy, fetus in situ in tube, abdominal cavity full of blood, good recovery."

Since this paper was practically finished Carl Beck of New York, records in the *American Journal of Obstetrics* for April, 1893, under the title "Ectopic Pregnancy twice in the same Patient" a case as follows:

"Dr. C. A. L. Reed of Cincinnati, had operated upon the patient on the 20th of March, 1891, and in a letter to Dr. Beck states that, 'I was called to see Mrs. M., by Dr. J. A. Johnson, who informed me that she presented the evidences of ectopic pregnancy. I made a section and found the abdomen full of blood. We took out a large number of laminated sacs from the cul-de-sac and removed the appendages from that side. There was a rent in the tube. There was nothing in particular about the operation beyond that which is peculiar to ectopic pregnancy. I did not find the fetus for the evident reason that the rupture had obviously occurred some time before and the fetus had disappeared by maceration.'"

"The woman was so thoroughly exsanguinated by the operation and by the loss of blood—that I had operated on the heels of a recent hemorrhage—for I made no search whatever for the appendage on the other side, which I believe ought always to be removed when practicable, and when not contra-indicated by an exsanguineous condition of patient whenever an operation is done for an ectopic pregnancy."

This woman came under the care of Dr. Beck on the 23d of August, 1892. She had missed two periods and believed herself again pregnant. On that morning she had a sharp pain in her abdomen and felt that she was going to miscarry. Her symptoms, which it is not necessary here to relate, led Dr. Beck to operate three days later.

He says: "A large tumor of fleshy appearance presented itself embedded in adhesions from all sides. It seemed to be the pregnant uterus, though the walls were very thin at the apex and fluctuating so markedly that I was not sure whether it was not the cyst of an extra-uterine pregnancy.

"On the right side a short tube about one-half of the normal length was seen ending suddenly in the large tumor. The ovary was normal. He incised the tumor and extracted the fetus and membranes of a pregnancy of over three months.

"When the fetus was removed the walls were easily seen to be hypertrophic and muscular, contracting and getting thicker, and by introducing my finger into the cavity I could distinctly feel the difference between the uterus and tube. The placental portion of the membranes had been attached to the tubal portions. An extirpation of the sac was, on account of the indistinct termination of the same, not possible without extirpation of the entire uterus. I therefore closed the incision by deep and peritoneal stitches."

In the discussion which followed Dr. Beck's paper (it was read before the Gynecological Society of Chicago) Dr. Fred Byron Robinson said that he believed that Dr. Beck's case "is a case of pregnancy in the horn of the uterus and not in the tube," and in this judgment I concur, although I have thought it wise to quote the case among those collected by me.

I am aware that not all of these cases are entirely proven. Yet observers, probably as capable of making a diagnosis as are those who will criticize them, and with the advantage of personally seeing the patients and the specimens, believed them to be cases of repeated extra-uterine fetation. But if even a very few cases were proven, the fact and the expectation and probability of like morbid or abnormal conditions prevailing in each of two symmetrical and identical organs excites the careful consideration of the initial question of this paper.

Now, if, in addition, we remember that Lawson Tait, Bland Sutton and others claim and apparently prove that many cases heretofore called "hematoma of the broad ligament" and "pelvic hematocele" are really ruptured tubal pregnancies, differing only in that rupture has occurred into different structures, and, further, that most cases of hemato-salpinx are the same conditions unruptured; and that a very large number of cases have been reported, in which, upon operation or autopsy after tubal pregnancy of one side, one of these conditions was found existing on the other side, we will see how frequent repeated tubal pregnancies are, and the facts will, I believe, justify me in the position I take and which I again state, that, in all cases in which, upon operation, a tubal pregnancy is found, the ovaries and tubes of both sides should invariably be removed.

Dr. H. J. Bowdler of New York City, related a case to impress the case which he held in opposition to the essayist, that, if the opposite tube and ovary were healthy, they should be removed to remain. Where, however, they were diseased, they should be removed in the class of cases under

discussion, just as during an operation for pyosalpinx or other condition.

DR. JOSEPH EASTMAN of Indianapolis, objected to operating on healthy appendages, because on one side there might be tubal pregnancy, and the danger of having to submit to a second operation was more than offset by the enhanced danger of the double procedure at the same sitting.

DR. HOWARD A. KELLY of Baltimore, thought especial attention should be given the pathological condition. The studies of his assistant pointed to crypts or diverticula in the mucous membrane of the tubes, sometimes observable under the microscope, as the cause of tubal pregnancy, the ovum becoming lodged in one and unable to pass to the uterus. But we could not say that this condition existed, making tubal pregnancy probable in a tube which appeared to be normal, simply because tubal pregnancy had occurred on the other side.

DR. HORACE T. HANKS of New York City; DR. C. R. REED, of Middleport, Ohio; DR. CHARLES P. NOBLE of Philadelphia; DR. J. HENRY CARSTENS of Detroit, and DR. A. McLAREN of St. Paul, favored removal of the appendages on the opposite side when they were diseased, but objected to the procedure when there were no indications of disease.

DR. O. B. WILL of Peoria, Illinois, had for several years been investigating the matter of catheterization of the Fallopian tubes, and had been able to demonstrate its possibility in a number of instances. He reported two cases in which the tubes were easily dilated, which he thought had a possible bearing on the etiology of extra-uterine or tubal pregnancy.

DR. McKELWAY, in closing, said the danger of removing a perfectly healthy tube and ovary, when an operation is being done for a ruptured tubal pregnancy had been exaggerated. It was not a difficult thing usually to remove a tube and ovary that were perfectly healthy.

EXTRA-UTERINE PREGNANCY.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY A. H. CORDIER, M.D.

KANSAS CITY, MO.

GYNECOLOGIST TO ALL SAINTS HOSPITAL; LECTURER ON CLINICAL GYNECOLOGY, KANSAS CITY MEDICAL COLLEGE.

A few years ago the report of a case of extra-uterine pregnancy was a rare event. They are frequent at this time; in fact, one can scarcely glance over a medical journal without seeing one or more cases reported. These cases are being recognized and reported with such frequency that one feels like apologizing to the members of a national organization for offering an addition to the list. However, it has been through the rehashing (so to speak) of this topic that this familiarity of the subject has been attained and the tabulation of these good results made possible. I shall dwell upon the pathology of ectopic gestation only so far as is necessary to sustain the position I hold, relative to the mooted location of the fetus in some instances, i. e. intra-ligamentous.

While my experience in extra-uterine pregnancy has not been an extensive one, it has been characterized by a multiplicity in number considering the length of time since I saw my first case.

In two years in my own practice and in that of others in which I assisted at the operation, I have had an experience of sixteen cases. The duration of pregnancy has extended over as wide a range as the location of the fetus has in variety; from six months to two years—from a soft gelatinous embryo to a

well formed nine pound child; from a columnar size embryo in the tube to a full grown child in the broad ligament. It is only in the tube ectopic gestation takes place and all other varieties are only made so by rupture of the tube as the fetus develops. Tubal abortion (?) being the exception, this may be excluded from the list with safety.

It is evident that all cases of tubal pregnancy rupture at some period, unless the growth of the fetus is stopped by some means, but the methods advocated to check the growth of the embryo are so uncertain in their results, so unsurgical and so dangerous to the mother, and the diagnosis so doubtful prior to rupture, that they are to be practically excluded from the management of these cases.

Intra-peritoneal is to extra-peritoneal rupture in the proportion of three to one. When rupture takes place between the layers of the broad ligament, the hemorrhage is limited by the resistance offered by the surrounding structures, death rarely occurring to the patient from this first rupture. The fetus may in this situation ("and in fact it is the only one in which it does," Taft) survive the accident and either continue to grow to the full period of gestation, or rupture secondarily into the peritoneal cavity, and cause speedy death of the mother from hemorrhage. Jesop's and Hoffman's cases of abdominal pregnancy were cases where the mother survived even this secondary rupture. The fetus dies, as a rule, after the primary rupture or at a later period before the ninth month, giving rise to suppuration in the leaflets of the broad ligament, leading to pelvic abscess, which may at any time burst into the peritoneal cavity, producing a rapid septic peritonitis and death, or it may open externally, by one or more fistulous tracts through the vagina, rectum, bladder or intestines. With rare exceptions the dead embryo becomes encysted and remains for years, placing the life of the woman in constant jeopardy. Cases terminating by suppuration are within the range of surgical interference.

When rupture of the tube has occurred it does not necessarily follow that all maternal and fetal structures be entirely and instantly separated and the embryo dislodged. This process when the rupture takes place into the ligament is as a rule a gradual one; some of the chorionis will remain attached to the tubal mucous membrane until the embryonic structures have established an independent existence, the child then continuing to grow; if this process of expulsion is a rapid one, then the fetus dies and an apoplectic ovum is the result, the hemorrhage is small and imprisoned or the bleeding may be profuse, killing the woman in a few hours. In the apoplectic as in the uterine abortion the hemorrhage is liable to occur at any time as long as the ovum is not removed. There is an authentic report (Taft) of a primary peritoneal pregnancy. The case is reported as such, where the child became viable. I believe were originally tubal, then intra-ligamentous, secondary rupture taking place converting it into an abdominal. In these cases the placenta will be found to occupy a position below the fetus usually in the bottom of the pelvis. When the tube ruptures into the peritoneal cavity the hemorrhage is always of the most profuse character, killing in many cases within a few hours after rupture, unless saved by timely and good surgery. In rare instances where rupture takes place and even where there has been

profound shock from the traumatic shock of the blood, the patient may rally and recover. The peritoneum is a wonderful resisting power, septic invasion of the poisonous material is against its outer surface. This minimal can be dilated and stretched considerably if only that process of gradual stretching. This is exactly what takes place during the slow growth of an intra-ligamentous pregnancy, where the pressure on the injury from the opening at the site of the tubal rupture has not been an abrupt process attended by a large hemorrhage. In intra-peritoneal rupture the first bleeding may not prove fatal, after giving rise to the most alarming symptoms; at any moment the hemorrhage may recur and kill the woman before the surgeon arrives.

A hemorrhage occurring in the peritoneal cavity differs from a bleeding occurring in any other part of the body; owing to the presence of more or less lymph in air-tight cavity the blood does not coagulate quickly and the clots that are formed are soft and friable and not of that character to firmly occlude the open mouths of the ruptured blood vessels and thereby permanently control the bleeding. They are easily washed away by the blood current with the increased force of the heart's action after the subject has temporarily rallied from the immediate depressing effects of the first hemorrhage. The treatment of this intra-peritoneal rupture may be summed in a few words: stop the bleeding promptly, remove the ruptured tube, wash out the cavity with hot sterilized water, and drain. The restorative agents and tonics should constitute the after treatment of these cases.

The diagnosis of ectopic pregnancy prior to rupture is attended with great difficulty and is rarely made; the symptoms are such after this accident has occurred that one can form an opinion warranting an exploratory incision down to the peritoneum. I say to the peritoneum, because if you are in doubt as to whether a serious hemorrhage has occurred or is going on, when you reach this serous membrane the correctness or error of your diagnosis is at once established and the proper course for you to pursue in the investigation or management of the case is at once mapped out. If this membrane is darkened or almost black and bulges through the incision you may at once know that a hemorrhage has taken place or is going on, or that there is some abnormal condition giving rise to the presence of a dark fluid, and the justifiability of carrying the investigation farther will be at once settled beyond a doubt. In many of these cases there is a history of some menstrual irregularity or deviation from the accustomed course in the case under investigation, such as the missing of one or two periods or an irregular intermenstrual period or flow occurring in a woman previously regular, culminating in an attack of acute suffering in the region of either uterine appendage accompanied by shock and symptoms of loss of blood.

Ectopic Gestation, Case.—Intra-ligamentous. Full-grown child retained nearly two years. Operation by Drs. Griffith and Cordier. Recovery.

Mrs. S., age 24. April 20, 1893, date of operation. April 15 I saw this lady for the first time. Says she has never given birth to a living child or had a miscarriage. Present health good. In August, 1890, she missed a period, having been regular prior to that time. In October no appearance of menses but in November flowed for three weeks, during which time she had pains in region of uterus of a paroxysmal character. Later in November she had "fainting spells."

and was semi-conscious for a few hours, but warm applications and brandy revived her. Never had any sickness at stomach. Breast became enlarged in December, 1891, with a darkening of the areole followed later by a secondary dark ring. Decidual shreds passed in November, 1891. She felt fetal movements in December, 1891, which continued up to April, 1892, or nine months after the date of conception. During March and April she had false labor pains with a steady flow of a watery looking fluid, with occasional small gushes; during this time she diminished some in size. Says enlargement was more on her left side in the beginning but soon became central. She did not have a regular menstrual period from August, 1891, to December, 1892. From November 1891 to April 1892 she had at times a "rusty discharge." She menstruated in December 1892 and was regular up to March 16, 1893. Since then (this is June 1) she has not seen her flow and the indications are that she is now pregnant. The pregnancy antedating the period of operation by four weeks.

This lady's mother consulted me in June 1892 relative to her daughter, stating that she had a "tumor of fifteen months' duration" and that she desired me to see the case. A few weeks later I asked the mother why the daughter had not been to see me; she stated that a physician had told the daughter that her "tumor" was a pregnant uterus. Said they were delighted to know that they were mistaken about its being a tumor. From this time the case dropped out of

my sight, but I thought of the case often as the history given me by the mother was a suspicious one and led me to believe at that time that it was an extra-uterine pregnancy. She returned with the daughter April 15, 1893 and I was called to see her with Dr. Griffith. At the time I saw her with Dr. Griffith she presented the appearance of a woman in the seventh month of pregnancy, fairly well nourished, good spirits and fairly good general health.

On examination we found a firm unyielding tumor extending two inches above the umbilicus centrally located, slightly movable, not painful to the touch or on handling. Dull on percussion, no fluctuation, no fetal or placental sounds. Digital examination located the uterus, a little enlarged, rather high under the growth to the front with the cervix pointing backwards. The tumor being posterior and to either side was under firm pressure slightly movable, giving the same resistance to pressure as was noticed on abdominal palpation. The diagnosis at this time was doubtful; the pregnancy gestation was the most acceptable one. When the incision was made down to the tumor, it was found that the knife cut down upon the growth at the point of the incision, no peritoneum existing at this point. The growth extending the cut upwards a peritoneal sac containing the growth was discernible and on opening this the contents were seen lying loose above the growth. The growth was removed and we found it was extra-peritoneal, as we termed it, in the depths of the broad ligament.

Now the difficult part of the operation began; the tying off and separating the omental adhesion was a slight task as it was adherent only in one place, but the entire capsule had to be tied in sections in order to remove the sac from its imbedded position in the pelvis. This could be done only by pushing a hemostat under a small section of this vascular membrane and tying it in sections by pulling a ligature (silk) through the opening made by the forcep, and tying it tightly. This tying and cutting process had to be carried around the middle of the tumor. On the upper and posterior aspect of the growth an intestine was found attached to the tumor for a distance of nine inches; this was brought about by the mass, as it had ascended out of the pelvis; stripping the peritoneum from the posterior wall of this cavity and separating the layers of the mesentery up to the gut by the same gradual process that had early in the pregnancy pulled apart the two layers of the broad ligament.

After making a complete circuit of the growth, the tumor was easily lifted from the bottom of the pelvis; this locality did not require a single ligature. During the

Mrs. S., four weeks after operation for extra-uterine pregnancy.

operation at one place on the tumor at the side next to the uterus (which was located as we had diagnosed) some very large vessels (arteries) were noticed, and at this same locality muscular tissue (Fallopian tube) was discernible. The tube at this location was evidently spread out and lost in the walls of the growth. Some remains of the organ of Rosenmüller could be plainly seen at this same location. At the left side of the uterus near the tubo-uterine junction the peritoneum was so firmly attached to the uterus that the organ was cut into and gave rise to considerable hemorrhage; this was controlled by a stitch or two and the membrane divided at a greater distance from the uterus. After the growth was removed the uterus was examined and found to be a little large with a sound tube and ovary on the left side, with the remains of a ligatured tube on the right side. The bottom and sides of the pelvis on the right side were stripped of peritoneum. The ureter and uterine artery could be distinctly felt immediately under the finger on that side. The bleeding from the surfaces was quite profuse but not alarming and was easily controlled by hot water. Irrigation and drainage used. The operation was a

long one but the patient left the table in good condition and two hours later had a pulse of 80. On examining the mass after its removal a full formed eight pound child was found in its interior. The sac surrounding the child had compressed it until the anatomical landmarks used in diagnosing pregnancy by palpation were completely obliterated—every nook and corner of the sac was filled with baby and placenta. The placental site was at the top of the sac, the cord down over the left eye of the child. The face of the child was turned to the mother's right side, the left shoulder and side of the face were the pelvic presenting parts. The body was strongly flexed, the feet being above the head, the breech pointing to the mother's right side.

The child had a complete envelope of its own and was beyond doubt primarily a tubal pregnancy which had ruptured into the broad ligament and in this location the child had continued to grow up to full term. The child then or soon after dying, remained encysted up to the time of operation.

The child was as well preserved as though it had been in a specimen jar of a well kept pathological museum. The liquor amnii had been absorbed; a small amount of meconium was found in the sac. No lime salts had been deposited in the child or its envelopes.

These cases are rare; a record of a case in the museum of the College of Surgeons of London says the child was retained for fifty-two years and was found to be as fresh and unaltered as a newborn child. In this case the specimen was removed postmortem.

I report this case in full because of its interest from a diagnostic and pathological standpoint. The steps of the operation and the results make it a unique case (barring the case referred to by Thornton, *Trans. Obst. Soc.*, Vol. xxiv, p. 81).

The sac, placenta and child were removed without opening the envelopes. The cases (except the one referred to by Thornton) heretofore, as far as I have been able to find out, have been treated by opening the sac, stitching it into the abdominal incision after removing the contents either in part or in whole.

This was originally beyond doubt a tubal pregnancy, and the manner in which the child reached its new location and continued to thrive and develop is certainly understood by any one acquainted with the anatomy of the mesosalpinx and its relation to the Fallopian tube. The rupture, which must have been a gradual one, took place early in the development of the embryo and on the under side of the tube, the fetus being gradually extruded or growing in the direction of least resistance descended between the leaflets, until it reached the floor of the pelvis.

She evidently had a hemorrhage about the tenth week; this bleeding was controlled by the pressure exerted by the broad ligament. The front and back layers becoming more and more distended by the growth of the child until on the right side the pelvis was robbed of its peritoneum, the bladder and part of the rectum also being denuded of this membrane. The remains of the tube were spread out over the sac thus assisting the broad ligament in roofing over the fetal membranes and their contents. The tubal mucous membrane plays a very trifling part in the forming of the placenta in ectopic gestation. The placenta in these cases is derived almost entirely from the fetal structures.

The villi are developed early on the outer side of the ovum and receive the blood from the allantois. These villi insinuate themselves into the folds of the tubal mucous membrane. With the growth of the ovum these villi increase in number and size, the mucous membrane becoming thinner as the tube dilates and less and less of this structure in any one locality enters into the make up of the fetal

attachments, so that ultimately the placenta when formed is, strictly speaking, made up only of fetal structures. In the case just referred to the placenta was situated at the upper side of the child and was pushed well up into the abdomen. This locality presents the most unfavorable site for the placenta to grow and nourish the child. Hemorrhages are more likely to occur in the latter months if the placenta is located above the child. This is due to the constant stretching of the peritoneum, producing a partial separation of the placenta the same as takes place in placenta previa. At the time of operating more danger is encountered from hemorrhage and wounding intestines if the placenta is situated above the child.

ECTOPIC PREGNANCY: ITS COMPARATIVE SYMPTOMATOLOGY AND TREATMENT.

Read before the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY JOSEPH HOFFMAN, M.D.,
PHILADELPHIA, PA.

Amid the conflicting claims as to the positive or presumptive symptomatology of ectopic gestation, the candid inquirer may very justly pause to join with another who long ago exclaimed: What is truth? In these days when hastily written reports are hurried into press, not to increase the general fund of information on a given question, but to call attention to the existence of the writer, too great care can not be taken to discriminate between opinions that come of experience, either practical or critical, and those that arise from accidental contact with cases of a certain class, not before met by the reporter, who consequently hastens to record his unique diagnosis and procedure, taking it for granted that his case is typical, and that his knowledge of the matter is therefore all-embracing and positive.

Nowhere is this aspect of affairs more urgent than in the advanced abdominal surgery of to-day. Opinions are held, stands are taken, contradictions are given to experience and logically adapted procedures, by those who have neither experience, nor the judicial mind to weigh the value of differences, failing in which their claims are ridiculous to those who know them, and terribly misleading to those confiding in them. Surgical results are not to be expected from neophytes or pretenders; neither from the results or claims of these are deductions to be made, except to mark their disastrous work as the shoals upon which life is lost and real surgery wrecked. At the beginning of our inquiry we are met with many difficulties arising, in addition to such as those cited above, from the fact that men in whom by name and reputation we are led to rely upon, are so widely at variance in reference to their expressed views relative to the diagnosis of ectopic gestation. So far as diagnosis is concerned, the term may be almost used synonymously with symptomatology, for upon the latter the former must depend, so that when we find a writer holding that there is a positive chain of symptoms, or a set of symptoms, in connection with which a physical examination will or will not point to the presence of ectopic pregnancy, we will find that he will also claim his ability to diagnose the existence of the condition. Winckel for instance, whose experience up to the writing of

his late book on obstetrics records an experience of thirteen cases, claims that the diagnosis is not so difficult, and substantiates his claim by the assertion that he had proved his diagnosis, either by the elimination of fetal parts or by autopsy. It may be here premised that a diagnosis that is made either by postmortem or by after-discharge of fetal bones, is scarcely to the purpose, and while valuable as pathological records, have no value from a surgical point of view, except to condemn and repudiate the reasoning that allows such procrastination with its unfavorable and unfortunate results. The misfortune is that those who most widely argue the possibility of exact diagnosis, have had the least, and in many cases the most meager, abdominal experience. They believe that it is possible to say positively that this or that swelling is the result of an ectopic gestation, because they do not understand the various train of pathological conditions that have their manifestation in pelvic fullness, tenderness, throbbing and the like. Failing to appreciate the multiplicity of such disorders, they naturally lay especial stress upon that which they are looking for, and accordingly find what they are seeking, not on account of their superior knowledge, but because of their greater inexperience. If it be true, as is generally conceded, that most of us make a diagnosis by exclusion, it stands out clearly that the less we have to exclude, the sooner to us is a diagnosis possible, or clear; hence we find that men who claim a positive symptomatology in this condition, are constantly making extreme errors, of which we only hear by accident, and when discovered, are explained away by the assertion that such errors were made by the unusual complications existing, when it is plain to the more experienced gynecologist, that this apparent exception only proves the rule, for in ectopic pregnancy the unexpected is always happening, and is at the bottom of all the discrepancies of opinion concerning it, where any experience has width sufficient for latitude of expression. If any one of us sets out with the idea that, given a certain train of symptoms, pointing in the main to an ectopic pregnancy, this is infallibly present, of course the diagnosis is always made; when it is missed the case is not reported. It will thus be readily understood that the impression of exact and uniform diagnosis is a totally unfair one, and that it is not at all to be relied upon. The trouble is, therefore, in the experience of the diagnostician as an operator. Theoretically the distinction between pregnancy natural, and pregnancy ectopic is so wide that only a fool could be deceived. Practically we know that often a most careful examination in the simplest cases can not decide the matter. Now when this is true of uncomplicated conditions, the difficulty at once increases in a geometrical ratio in complicated ones. We must remember that pregnancy, whether intra- or extra-uterine, is not the only condition that causes enlargement, swelling and softening of the uterus. All these conditions are simulated by totally variant causes, having nothing at all to do with gestation in any form. If now we go on to the other recognized symptoms, such as suppression of the menses, irregular periods, nausea, swelling of the breasts, we shall find that all of these are simulated in miliary disease of the ovaries, and that in addition there is here an ectopic swelling, lateral or retro-uterine, with tenderness and throbbing totally misleading except in the unmarried,

while in other cases, only the probability is diminished, and the diagnosis is not certain. In these cases, too, another misleading feature is the uterine discharge, for this is so irregular that it will be impossible for the most careful observer to decide positively whether the decidua has been expelled or not. To cap all, the temperature is misleading. Nor is this the only perplexity, for the size, softness, and appearance of the uterine structure, all suggest pregnancy. Running parallel with these symptoms, are those of the stomach, than which nothing can be more capricious, and taken together with the frequent abdominal tenderness, often amounting to well developed attacks of peritonitis, the symptomatology of ectopic gestation is so near complete, that nothing farther in the majority of cases would suggest itself. Probably the most misleading cases of all, are those in which there is ectopic, complicated by pelvic tumor of another sort, or where there is true pregnancy, with pelvic inflammation, tubal or other, or where both intra- and extra-uterine pregnancy are associated. The operator who has met these conditions, can always be relied upon to confute the vaunted easy diagnosis. As I have before noted, theoretically the diagnosis is easy to differentiate, while practically, it is most perplexing. A case of my own may be here cited with profit. A woman thirty years old, one child eight years old, never after pregnant. Menstruation not missed, was taken with violent abdominal pains, with some discharge. Examination revealed a uterus slightly enlarged, so far as could be distinguished, through thick abdominal walls. The lateral tenderness was especially marked on the right side, and the whole abdomen was tender and swollen. The bowels were freely opened, but in spite of this, the pain, swelling and rise of temperature continued. The odor of the discharge was distinctly placental. Operation was decided upon, with diagnosis of ectopic pregnancy. The condition revealed was double sided pyosalpinx, and peritonitis, combined with pregnancy, which indeed was so obscure as to be questioned by my assistant, who being present will no doubt refer to the case. The appendages were angrily inflamed, and nothing was to be done except to remove them. The woman made a good recovery, in spite of her miscarriage four days after operation. There will no doubt suggest themselves other steps, to have confirmed or negated the diagnosis, but these may be noticed in the discussion. The diagnosis of ectopic pregnancy in the presence of fibroid tumors of the uterus, is an exceedingly interesting topic. Strahan makes the exceedingly naïve criticism that it is hard to understand how with bi-manual examination, and a little common sense and prudence, a mistake could be made between the early stages of extra-uterine gestation and a small fibroid of the uterus. But the matter can not be thus lightly dismissed. The poet has it, that

"Experience joined with common sense
To mortals is a Providence."

The common sense may be of the best, but if the providence be not present in the shape of experience, alas for diagnosis. Not only may an intra-mural fibroid simulate an interstitial pregnancy, without pregnancy, but it may produce abortion in natural gestation; and afterward, the tumor still persisting, may simulate an interstitial ectopic pregnancy. The simulation is all the more complete, because mam-

mary symptoms, hemorrhage, and uterine spasm, all combine to mislead the physician. Pregnancy in a fibroid tumor, which, after conception, has taken on a rapid growth, when the portion of the uterus containing the fetus is posterior or lateral, or after the fetus has died, may puzzle the most skilful diagnostician. Not only are the cases in which true pregnancy exists thus found to be difficult of diagnosis, but a second class of cases arises, in which there is no pregnancy at all, but ectopic is speciously simulated—to wit, in dermoid and ovarian cysts. Ovarian cysts have again and again been diagnosed as ectopic pregnancies, while dermoid tumors even after removal in postmortem examination have been recorded as such, as is instanced in Campbell's "Memoir on Ectopic Gestation." A case of ectopic gestation on one side with a dermoid tumor on the other side of the pelvis has come under my own notice for operation, and it will be readily understood how a more misleading state of affairs could hardly exist. If the dermoid contain fetal bones, and other debris, digital examination may do little more than perplex. In these cases miscarriage after miscarriage is apt to supervene, and the tumor persisting, after the discharge of placental debris, as is a common occurrence in ectopic gestation, the diagnosis is easily reached of ectopic pregnancy. One such case has come under my care, in which the diagnosis of pelvic tumor was made, but from my present knowledge of the subject I could hardly escape the suspicion of ectopic gestation, and suspicion in these cases often is the sum total of diagnosis. In any pelvic tumor, where suspicion points to ectopic pregnancy, I take it that operation should settle the diagnosis in competent hands. Where the growth has been rapid, it does not necessarily follow that the case is one of ectopic pregnancy, for fibroids may take on an almost mushroom celerity of growth, and the same is true of cancerous disease. In the latter condition, however, cachexia is an almost unfailing symptom which should be a great aid in differentiating it from ectopic pregnancy.

Diagnosis.—We have now reached a position where an opinion as to the merits of positive diagnosis may be reached. We may say, then, that here we have a disease in which the probability of its presence can often be safely affirmed, after certain periods: first after rupture; second, after the fetus has become viable; third, in the presence of discharging fetal remains either through bladder, rectum, or umbilicus. It is almost ridiculous to consider the last condition under the head of diagnosis. As to the diagnosis previous to rupture, since a majority of cases are called to our attention subsequent to rupture, and since it is the rupture that attracts attention to these cases, it follows that if a diagnosis is made, it must be in the minority of cases. The simple fact that of all ectopic pregnancies so few come under observation for treatment or examination, unless we except the so-called electrical cures, must of itself stand a challenge that there are any symptoms which are so peculiar as to excite the attention of the women in which the accident occurs. When even rupture occurs, most women consider that they have an attack of colic and when the decidua is passed, they regard it as a miscarriage. That itself may be a most misleading symptom to the physician. The diagnosis therefore of the remaining cases, is best considered from the standpoint of the symptomatology, to which

we have already devoted considerable attention. To repeat, the diagnosis must be after the conclusion that a pregnancy exists. First in these cases, we must say that the symptoms are those of ectopic gestation, for be it remembered, normal pregnancy must be excluded.

Winckel's assertion that ectopic gestation is more readily diagnosed than the normal condition is one that is safely left with himself. It is hardly worth while to dispute it. The misfortune is that this German author claims a position which I, for one, hesitate to assign him. His abdominal experience does not justify his sweeping statements in diagnosis. If from the date of a supposed conception, of sexual congress, in cases whose exact pelvic condition was previously known, we could have our patients constantly under observation, there is no dispute that pregnancy if it occurred, whether ectopic or normal could be diagnosed. But this status of affairs is for the most part impossible and can not enter into our calculations. In the cases therefore that come under our hands for diagnosis, previous to rupture of the ectopic cyst, all the contradictions and variations in the symptomatology noted above, must be accounted for, and the greatest latitude allowed for irregularity in symptomatic expression. In a patient of my own, suffering with frequent miscarriages, I found the following condition: Taken with a sudden attack of pain she resorted to ordinary remedies. I saw her a few hours after the attack. She had complained of anteceding pain on the right side. Her catamenia had failed for two months. When I saw her there was a slight show of blood, and she was in collapse. She had done a large washing during the day upon the evening of which I was called to her.

Treatment.—After the futile resort to mere experiment in dealing with this dread disease—delay, puncture by electricity, electricity without puncture, and puncture with injections of morphia, still with their advocates—I can do no better, nor pay a more fitting tribute to our Stephen Rogers, who rising above, before the recognition of the possibilities of abdominal surgery, and cleaving with an inspiration of surgical good sense, the superstition of the accepted fatality of this disastrous accident, enunciated his belief in these words:

"The peritoneal cavity must be opened; the bleeding vessels must be ligated. He, indeed, must be a madman who under such circumstances would neglect anything in his power to secure the chances such an operation would afford of saving the life of his patient."

THE ELECTRICAL HORSEWHIP.—It seems doubtful whether objection can be brought against the latest form of horsewhip, which is constructed so as to give a slight electrical shock to the animal. The handle, which is made of celluloid, contains a small induction coil and battery, the circuit being closed by means of a spring push. The extremity of the whip consists of two small copper plates insulated from each other, each of which is provided with a tiny point. The plates are connected with the induction coil by means of a couple of fine insulated wires. As a means of surprising a sluggish animal into doing his best work without the infliction of physical pain the electrical horsewhip will by many be hailed with gladness.—*Hertford Times.*

METHODS OF REMOVING THE UTERUS FOR UTERINE FIBROIDS, WITH REPORT OF CASES.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY J. N. MARTIN, PH.D., M.D.

PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN, UNIVERSITY OF MICHIGAN, ANN ARBOR, MICH.

Notwithstanding the free use of drugs, such as ergot, cannalis indica, etc., in various ways, and notwithstanding the persistent use of electricity with all of the modern appliances, there are many uterine fibroids that are but slowly or slightly altered for the better; and a large number continue to grow with increasing deleterious results, despite the use of these agents.

This leaves a large and, as I have found from experience, a difficult field for surgical work.

This short paper is devoted exclusively to the practical surgical side of some methods of removing the uterus to get rid of these perplexing growths.

These methods in their different phases I will illustrate briefly with cases, that I may show more clearly why we adopt different lines of procedure in operating upon this class of patients, and also to demonstrate that it is difficult or impossible to formulate a definite plan of action in some until the operation is already begun and we can see the intra-abdominal relations of the tumor.

I believe that a tumor causing sufficient trouble to warrant a laparotomy is so far incorporated with the uterine walls, as a rule, as to necessitate the removal of the uterus.

Rarely, we find a simple case—a sub-peritoneal tumor with loose attachment that can be easily removed. It has not been my good fortune to meet many such easy cases.

In many cases it is best or necessary to remove the uterus with the tumor. This is the great and difficult field for surgical work in dealing with uterine fibroids. It includes the large ones, the multiple ones, the fibro-cystic ones, the complicated ones and nearly all of those that are death-dealing to our suffering patients—if they are not removed by surgical means.

It requires more nerve and more skill to deal with them properly than is required in almost any other field of surgery. The operation in the beginning may be comparatively easy, and before completion be prolonged into hours of the most careful, skillful, difficult and nerve wearing work imaginable. One who has entered this field realizes this fully, and one who contemplates crossing its threshold should be prepared to meet all the complexities that the worst case presents; for such he may find his first case to be, before his operation is successfully completed.

Some of the most troublesome fibroids to deal with are the intra-ligamentous ones that unfold the broad ligaments, displace organs, and are prone to form numerous and large adhesions. My experience with these teaches me that they are very vascular from original attachment and from vascular adhesions; for they grow more rapidly and cause more pain.

In some cases the difficulties in treating these surgically are almost insurmountable. I begin the operation with a sub-peritoneal incision by incising the peritoneum over the tumor from side to side, and then strip

it down anteriorly and posteriorly with my hands and turn the tumor out slowly, ligating and cutting adhesions; being sure to ligate the ovarian and uterine vessels and then sever as much of the broad ligament as is necessary to liberate the tumor and tumor side of the uterus. After the tumor is liberated, except the uterine attachment, pull it up and toward the side on which it developed; then proceed to ligate the ovarian vessels on the opposite side and cut the ligament under the tube and ovary, preventing reflux with long forceps, à la Baer.

Afterwards ligate the uterine vessels, then strip down the peritoneum in front and behind the uterus, being sure to incise it across, a little above the bladder (an inch or so); about the same or little lower behind. The next step will depend upon the condition of the patient, the relation of the tumor to the lower zone of the uterus and the cervix, and how certain I feel concerning the control of the hemorrhage. If I feel sure there is no danger of hemorrhage, I cut away the uterus and tumor without the elastic ligature or *serre neud*, provided the tumor is high enough for a pedicle below it. If I fear hemorrhage, I apply the *serre neud* and test the condition. If there is some oozing, tighten the *serre neud* slightly, trim the stump with wedge-shaped cavity, leaving two flaps which are coapted with deep interrupted catgut sutures and the peritoneal edges with superficial catgut sutures, and then remove the *serre neud*.

Before coapting the flaps, I cauterize the cervical canal and fill it with iodoform. In the last case I passed iodoform gauze through the cervical canal, and left the end loose in the vagina.

If there is still oozing after flaps are united by sutures, pass deep ligatures around the outer fourths of the stump and tie. Then drop the pedicle back and unite the anterior and posterior folds of peritoneum with catgut sutures to insure against the intestines dropping into the fresh wound.

If there is oozing, and the patient's condition requires speedy termination of the operation, apply the *serre neud* and fix the stump in the lower abdominal wound if the pedicle is long enough. If it is not long enough, ligate the outer fourths with strong silk, or the whole pedicle, and cauterize the end of the stump thoroughly according to Dr. C. T. Parkes, and with a few stitches unite the peritoneal folds.

The following cases will illustrate these points:

1. Operated upon Jan. 6, 1892. Married twenty-two years and sterile. Upon examination a hard tumor was found filling the pelvis and extending two inches above the umbilicus. After abdominal incision, I incised the peritoneum laterally from side to side, separated the tumor and uterus from the bladder and rectum, tied off the adhesions, applied the *serre neud* and removed the tumor, uterus and its appendages. At this time the patient developed unfavorable symptoms and I hastened the completion of the operation by fixing the stump in the abdominal wound. The shock proved to be of short duration; the patient made an excellent recovery and is now well and happy.

The next case was operated upon the last of February, 1892. Upon examination a uterine fibroid was found that filled the pelvis and extended to the sternum. The patient was greatly emaciated, pale and very weak. On account of the many adhesions, the operation required two and a half hours of hard work. She stood the operation fairly well, consider-

ing her weak condition, until near the close, when all but the cervical attachments were severed, and then she showed marked signs of collapse. I applied the *serre-neud* quickly, cut away the tumor and uterus and fixed the stump in the abdominal wound. The tumor weighed forty-two pounds and had one cyst that contained twenty-eight and one-half pounds of pus, as Prof. Gibbs' examination showed. The patient made a rapid recovery, and went home well six weeks after the operation. I believe both of these cases would have been lost by prolonging the operations after these alarming symptoms arose.

When the tumor is not intra-ligamentous and the relations and conditions are such as not to demand total extirpation of the uterus, but the cervix may be left, I remove the tubes and ovaries with the uterus as previously described.

Ligate the ovarian and uterine vessels, cut across the uterus anteriorly and posteriorly, strip down the peritoneum and separate the vesical fold and bladder, also the rectal fold; then ligate bleeding vessels and cut away the uterus and tumor, remove wedge-shaped piece, cauterize the cervical canal, dress with iodoform, coapt the flaps of the pedicle and the peritoneum, unite the peritoneum over the wound; all to be done after the same manner and with the same precautions as previously described. In all such cases, drain from the posterior cul-de-sac into the vagina with a glass drainage tube for from four to seven days.

The six cases in which the stumps were treated intra-peritoneally were operated upon May 28, Oct. 19 and Nov. 26, 1892; Feb. 18, March 11 and April 26, 1893.

The one operated upon Feb. 18, 1893, died from cerebral cause and is reported later in this paper. In the one operated upon March 11, 1893, the drainage tube came out the second day after the operation during an attack of coughing and was not replaced. This resulted in rapid closing of the opening, retention of the secretions and elevation of the temperature to 102 degrees. The tissues were separated and a rubber drainage tube was inserted and kept in four days. Seven hours after its introduction and irrigation with a sat. sol. of boracic acid the temperature was 99 degrees, and the patient made a good recovery.

The other four cases made uninterrupted recoveries.

Sometimes the fibroid forebodes malignancy or is incorporated with the uterine walls so low down as to necessitate total extirpation of the uterus. Four of my cases were such that total extirpation of the uterus was the only procedure left me.

In one case operated upon May 2, 1893, the cervix was spread over the tumor and enlarged uterus so that it did not project a half inch from the surface of the hard mass. Upon vaginal examination a round, hard mass the size of an infant's head at birth could be felt filling the pelvis, and it extended up to the umbilicus.

Three other cases under this head which were operated upon more than a year since, Dec. 30, 1891, Feb. 17, 1892, May 19, 1892, had tumors ranging in weight from eight to over twenty-six pounds. They involved not only the body of the uterus, but the cervix as well. These were all intra-ligamentous, and were long and exceedingly difficult operations.

When total extirpation, or Eastman's method, is decided upon, I draw up the tubes and ovaries and clamp below them with long forceps to prevent reflux,

tie off the broad ligaments in sections as close to the uterus as possible, being sure to ligate the large ovarian and uterine vessels with strong silk, leaving one end of each ligature long, so all of them can be brought into the vagina, and by traction on them the stumps can be turned down into the vaginal opening. Some object to this method of leaving the sutures, and I question it sometimes; but the results are good. I use long forceps along the sides of the uterus to prevent reflux from the uterus during the operation.

Before ligating and cutting the lower segments of the broad ligaments, I incise the peritoneum across the uterus in front and behind, strip down the peritoneum with my hands and blunt instrument and separate the bladder and bowel. Then perforate the vagina with forceps and incise the vault of the vagina anteriorly and posteriorly with blunt pointed bistoury or scissors, with the fingers of the left hand in the vagina to guide them, and then tie all bleeding points.

Finally, ligate the lower segments of the broad ligaments with strong braided silk (avoiding the ureters), and cut them and remove the uterus and the tumor.

In two cases I was obliged to apply the *serre-neud* temporarily and to cut away most of the tumor and uterus before I could remove the cervixes, as the tumors were so large.

After the uterus and tumor are removed, wash out thoroughly with sterilized water, draw the ligatures down and invert the stumps; dress with iodoform gauze. Unite the peritoneal flaps in the wound with interrupted catgut sutures.

If the patient's condition is bad, the operation may be shortened considerably by clamping the lower segments of the broad ligaments with forceps per vaginam and leave the forceps on a few days. Remove the ligatures when they separate, in from six to fourteen days.

Dr. Byford's method of treating the stump by vaginal fixation is no doubt good, as his results show, but I have not practiced it, and, as it has been described so often I will not repeat it here.

In all cases, the abdominal wound is to be closed and treated as in any laparotomy, and the patient is to be prepared the same for the operation, except the vaginal cleansing must be more nearly perfect.

Of thirteen hysterectomies for fibroids, two died. Of the two that died, one had a tumor that filled the pelvis and abdomen and extended up to the sternum. The abdomen was as large as a large full term pregnancy; her circumference at the umbilicus was forty-six inches. In order to deliver the tumor, it was necessary to make an incision from a little above the pubis to the ensiform cartilage and laterally through one rectus muscle. There were numerous and large adhesions binding the tumor to everything within its reach. The uterine cavity was seven inches long.

It was a long and difficult operation on account of the many adhesions, difficulty in delivering the tumor and the numerous bleeding points.

The patient died of shock the following day. This was a total extirpation.

The other patient died eight days after the operation. Everything progressed favorably for seven days, when she suddenly became paralyzed on one side, and the next day she died. Evidently a cerebral cause. The other cases have made good recoveries.

In my work in this line of surgery I endeavor to be aseptic, and to combine what seems to me the best points gleaned from observing the work of eminent American and European gynecologists who are abreast of the times.

I do not believe in any "new method," so-called, for removing the uterus for fibroids, unless it specifies the special conditions and cases to which it is adapted, for then only is it of value.

I believe there is no one method, new or old, adapted to all, when we consider present relations and ultimate results.

I approve that method with conditions favorable which leaves the cervix and its stump treated intra-peritoneally and the lower segment of the broad ligament, for the following reasons, viz:

1. It leaves a stronger floor for the pelvis, and it leaves the vagina in a better condition than when the cervix is also removed.

2. It is better than fixing the stump in the abdominal wound, as it permits of free dilatation of the bladder and there is no traction. The recovery is more rapid, as there is no sloughing mass left to separate and interfere with the healing of the abdominal incision. The operation can be completed with a shorter pedicle.

3. The vagina is left in a better condition than with Byford's method. By his method, the cervix and tissues about are twisted out of shape and a mass is left to separate. However, if this method is to be adopted it is necessary to be sure of the control of the hemorrhage, exercise perfect aseptic methods in the operation and toilet, and to be certain, drain from the posterior cul-de-sac.

Appendix.—Since writing the above, I did my fourteenth hysterectomy, May 23. There were seven fibroids attached to the uterus, ranging in size from a hen's egg to an infant's head. The entire mass was wedged tightly into the pelvis. The patient is making an excellent recovery.

PORRO-CESARIAN SECTION.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY J. H. CARSTENS, M.D.

PROFESSOR OF OBSTETRICS, DETROIT (MICH.) COLLEGE OF MEDICINE;
GYNÆCOLOGIST TO HARPER HOSPITAL, ETC.

Having had the pleasure of reporting a successful Porro-Cesarian section in the *American Journal of Obstetrics* last year, it is peculiar that I should be able to report another case within six months. The second case is as follows:

Mrs. S. is 23 years old; her mother died of pneumonia at the age of 55; her father is living and healthy; she has two brothers and three sisters living; one of the latter had six children, the other had five. They were always delivered by a midwife. Mrs. S. is of German parentage, but was born in this country. In the fall of 1891, I was called upon by Dr. W. J. Brand to help him deliver her. She had been under the care of a midwife for twenty-four hours when he was called, and failed to deliver her with forceps. As the child was dead the only thing to do was to perform craniotomy. Even after craniotomy it was quite difficult to deliver on account of the narrowness of the pelvis. When this was finally accomplished I took careful internal measurement with the pelvimeter and found an antero-posterior diameter of less than three inches. She made a slow but

good recovery. We told her that if she ever became pregnant again that it would be necessary to bring on a premature labor. She was very anxious to have a child and did not think that a seven months child would live, although told of the danger and need of Cesarian section if she went to full term. She kept very quiet when she again became pregnant and only told Dr. Brand two weeks before her expected time. It was then too late and we made all preparations to take her to the hospital as soon as labor should set in.

September 24, 1892, she was taken with labor pains, so we took her to Harper hospital in the ambulance at 8 p.m. I wanted to wait with the operation until in the morning, but found that the cord was presenting and being afraid that compression might kill the child before morning I decided to operate immediately. She was prepared as for any abdominal section and I operated at 9 p.m. in the presence of many physicians of this city. The bag of waters was first ruptured and then the usual incision was made. The uterus was rolled out à la Müller, an elastic ligature applied, then the uterus quickly opened and the child weighing 8 pounds removed. I was undecided to do a Porro- or a so-called classic Cesarian section. All the physicians present were unanimous for the Porro, hence I applied a clamp. I removed the uterus, tubes and ovaries. The after treatment was like any other coeliotomy and her recovery smooth, as the Germans would say. She nursed her child from the first and left the hospital twenty-five days after the operation. To-day she is the picture of health, as well as her child.

The only question in my mind is, whether we should do a Porro or preserve the uterus? If the child had been dead I would have done a so-called classic Cesarian section. Still the life of one child always hangs on a thread and her future chances for motherhood are destroyed in my patient. What shall we do? If we preserve the generative organs, the woman will again and again become pregnant and she must be repeatedly subjected to the most critical operations of surgery. Is this right? Is it desirable to propagate the hereditary tendency? The moral questions involved are still in doubt in my mind, hence I wish a thorough discussion by the able members present.

You will, of course, see that I am inclined to the Porro because: 1, it can be quickly performed. 2, it is less dangerous. 3, the woman's future is free from such dangerous operations.

THE CAUSATION OF THE DISEASES OF WOMEN.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY CHARLES P. NOBLE, M.D.
PHILADELPHIA.

Within recent years activity among gynecologists has taken the form of improvement in the technique of operations; and as an outgrowth of the large number of operations which have been performed, the pathology of diseases of women has likewise been improved. Comparatively little has been written concerning the causation of the diseases of women, although the subject is one of great importance, in view of its bearing upon preventive medicine. Only as the causes of disease are made known to the profession at large, is it possible to take measures for their prevention. And in gynecology, especially, prevention is far better than cure.

The principal causes of the diseases of women are:

1. Imperfect development of the sexual organs.
2. Gonorrhea.
3. Septic inflammation following child-birth.

4. Lacerations due to child-birth.

5. Miscellaneous causes, including constipation, erroneous habits of life, and errors of dress.

1.—*Imperfect Development of the Sexual Organs.*—

The influence of imperfect development of the sexual organs as a cause of diseases of women, cannot well be over-estimated. At the present time not so much is said of the influence of this factor in producing disease, because it has been more or less lost sight of since tubal and ovarian pathology has so much occupied the attention of gynecologists. The experience of every observant practitioner demonstrates the prevalence of imperfect development, and also its influence in producing various diseases of women. As a rule, when the development of the sexual organs is arrested, the development of the body, as a whole, is also interfered with. Such women, almost without exception, belong to the class of neurotics, and they are especially liable to all manner of neuroses, including, especially, chorea, headache and neuralgia. The most striking signs of this condition are the late development of puberty, the imperfect and painful character of menstruation, and the fact that the history of semi-invalidism, almost without exception, can be obtained. Puberty is often delayed even as long as the eighteenth or nineteenth year or longer. Menstruation is always painful. The pain belongs to the type of so-called ovarian dysmenorrhea; that is to say, it begins one or several days, or even a week, before the menstrual flow, and is felt especially in the ovarian regions. Reflex neuroses are common accompaniments, especially headache, disordered digestion, or even sick headache. Uterine dysmenorrhea, due to the undeveloped condition of the uterus (especially of the cervix) which is in general sharply anteflexed, is frequently present. This is indicated by its paroxysmal character, and by the fact that, as a rule, it is much less marked after the flow has become fully established.

The reason why the development of the sexual organs of girls becomes arrested is not absolutely demonstrated. The influence of modern education as a cause has been much dwelt upon, and the evidence in support of this theory is very strong. The effect of the crowded courses and frequent examinations in our schools in developing the nervous system at the expense of the rest of the body, and later in breaking down the tone of the nervous system through over-work, has been abundantly proved. The emotional side of the female character likewise is stimulated. As a result of these conditions the digestion of growing girls is apt to become deranged, and their sleep likewise to be disturbed. As a further consequence anemia and depraved nutrition follow, aggravating the neurotic conditions already engendered and thus completing the vicious circle. When such girls arrive at the age of puberty, especially if at the time they are being crowded with a multiplicity of studies to enable them to enter a fashionable finishing school, the demands upon the nervous system to enable them to accomplish their tasks are such that the processes which are necessary to bring about the proper development of the sexual organs are not brought into play—enough vital force is not left over to accomplish this result. The testimony of urban practitioners is unanimous upon this point, hence it must be considered as established that too great mental occupation directly hinders the development of the sexual organs. And not only

that, but at the same time breaks down the tone of the general nervous system.

Other causes, however, must be considered. Some of the most marked cases of arrested development of the sexual organs which have come under my notice have been among the poor. These girls not only had not been forced at school, but in not a few cases they had never been to school. In some of them it seemed to me that the cause was too early and too laborious work, especially in mills. I have had numerous patients among mill operatives who had gone to work as children in mills, and who had worked full time during the years when the greatest development takes place. In these girls it was probably a lack of fresh air, of out-of-door exercise and of an abundance of nutritious food, together with too much work that was at the bottom of the difficulty. A curious class of cases but little understood is that in which extreme corpulence is present. I have seen numerous cases in which menstruation was tardily established, never perfectly performed, and which ceased or became scanty and irregular between the twentieth and thirtieth years. Whether the imperfect character and early cessation of menstruation was due to obesity, or whether the obesity was due to the absence of menstruation I have never been able to satisfy myself. However, my own experience fully confirms the current opinion that obesity bears a certain relation to scanty and imperfect menstruation. The development of the sexual system in women is one of the mysteries of nature and the exact forces which bring it about will probably never be perfectly known, but it is rational to believe that the existence of good health about the time of puberty has much to do with its proper development. The care of growing girls, particularly between the age of nine and sixteen years, is a subject of the utmost importance, and the profession has no more urgent duty than to instruct mothers concerning the importance of the proper care of girls during that period. Girls who are inclined to be neurotic, and whose digestion and nutrition are at fault should not be treated in the same way as their stronger and more phlegmatic sisters. Their duties at school should be lightened, they should be more in the open air, and any functional disease which may exist should be cured. In this way some surplus vital force may be stored up to be called upon when necessary in the development of the sexual system. Also, when menstruation fails to appear at its accustomed time special care is necessary. It is at this time that therapeutics has the best opportunity to influence the patient. The health of all such girls should be carefully inquired into and all indications for treatment should be met. In particular, the administration of iron, arsenic and strychnia, and out-of-door exercise are to be commended. Such cases should not be lost sight of until menstruation is fully and perfectly established. I feel confident that if this plan be carried out, there will be fewer cases of dysmenorrhea and sterility upon the one hand, and of laceration of the cervix and perineum upon the other, and also fewer cases of chronic ovaritis and ovarian cystomata. I have purposely not made mention of the higher grades of imperfect development, and of the cases in which one or more of the sexual organs are entirely absent. These cases belong to a different category, from the standpoint of practical medicine.

2. *Gonorrhea.*—The fact that gonorrhea is a dis-

ease of women has, of course, been known for centuries, but a full knowledge of the course and results of the disease is a matter of the immediate present. Bernutz was the first author who had a proper conception of the disease, (about 1850). His knowledge was acquired as most of the exact knowledge of medicine has been acquired, by the postmortem study of cases. As physician to the Lourcine hospital, where he had a large venereal service, he had ample opportunity to study the disease. In his analysis of the ninety-nine cases of pelvic-peritonitis, upon which he bases his exposition of the subject, he gives as a cause of the condition, gonorrhea in twenty-eight cases.

Forty-three are considered to be puerperal, twenty menstrual and eight traumatic. Of the remaining twenty-eight non-*puerperal* cases there can be no question, when reading his report in the light of modern knowledge that almost all of them were gonorrheal. Bernutz, who was a very careful and accurate observer, cautions his readers against drawing the conclusion that so large a proportion of cases of pelvi-peritonitis (inflamed tubes and ovaries with secondary peritonitis) are gonorrheal in origin. He states that in his opinion the reason why this proportion existed in his cases was owing to the character of the hospital in which they were observed. Bernutz fully recognized the fact that gonorrhea not only involves the vulva, urethra, vagina and womb, but also the Fallopian tubes, the ovaries and the peritoneum. He reports numerous cases amply demonstrating these facts and treats the entire subject in a most intelligent manner. His observations, however, failed to make much impression upon the profession and it was not until Noeggerath, in 1873, published his paper on "Latent Gonorrhea in the Female Sex" that attention was called to the very serious ravages of gonorrhea in women. Prior to that time gonorrhea was looked upon as a mere trifling vulvo-vaginitis, of importance principally because of the fact that the disease might be communicated to men. The views of Noeggerath encountered much opposition and their spirit was not fully accepted until their truth was demonstrated by the work of the modern abdominal surgeons. It is now fully established that gonorrhea is one of the most important causes of uterine, tubal, ovarian and peritoneal inflammation. Exactly what percentage of cases of inflammation of the uterine appendages is due to gonorrhea has not been determined, although unquestionably the percentage is not inconsiderable. The opinions and experience of surgeons differ widely with reference to this question; and there is good reason to believe that the percentage depends upon the character of the community in which the surgeon resides. Urban communities containing large numbers of the poor and the vicious, and of the rich and immoral, undoubtedly have a higher percentage of cases due to gonorrhea than rural communities having a more decent population.

3. *Septic Infection following Child-birth.*—The results of septic infection in child-bed have been so abundantly dwelt upon since the days of Oliver Wendell Holmes and Semmelweis that one can not, at this time, hope to offer any new ideas upon the subject. Increasing experience only serves to demonstrate the serious results of this accident. It is necessary to refer here to fatal puerperal septicemia. We shall concern ourselves only with those

cases which have not had a rapidly fatal termination, and which concern the gynecologist as much or more than the obstetrician. Septic vaginitis, endometritis and metritis are well-known forms of puerperal inflammation. They frequently persist and require treatment after the puerperal period. Aside from the rapidly fatal cases, the most serious result of septic infection during labor is the spread of the septic inflammation to the uterine appendages, giving rise to salpingitis, ovaritis and peritonitis. This condition probably at times ends in perfect recovery. More usually it results, either in chronic inflammation of the appendages with the formation of adhesions to the neighboring structures, or in collections of fluid—serum, blood or pus—in the tubes or in the ovaries. The relative frequency of puerperal septic inflammation and of gonorrhea as the cause of inflammation in the uterine appendages is a mooted point. Most surgeons believe that the puerperal inflammation is by far the more frequent cause; others hold that gonorrhea is the more frequent cause, and they point out that inflammation of the uterine appendages following labor need not necessarily be puerperal in origin, because the puerperal inflammation itself may have been set up by a preëxisting gonorrhea. That this last claim is to a certain extent a valid one my own experience tends to show; but many accurate observations must yet be made before it can be determined with what frequency existing gonorrhea is the cause of inflammation in child-bed.

Another, but far less frequent result of puerperal infection, is acute inflammation or abscess of the broad ligaments—acute puerperal cellulitis and true pelvic abscess. Inflammation of the connective tissue of the broad ligaments formerly was believed to be the common form of puerperal inflammation outside of the womb; but when abdominal surgeons proved that what had been called *chronic cellulitis* in the non-*puerperal* state was in reality diseased uterine appendages, the tendency was to take extreme ground and to deny the existence of *acute puerperal cellulitis* and true pelvic abscess.

In addition to the varieties of puerperal inflammation described we have cases of phlebitis, and its associated condition, *phlegmasia alba dolens*.

As already remarked, it is not positively known what percentage of cases of tubo-ovarian inflammation is due to puerperal septic inflammation; but it is known that the percentage is a high one. Gonorrhea and puerperal sepsis together cause 95 per cent. of all cases of tubo-ovarian inflammation. The importance of this fact from the standpoint of preventive medicine can not be over-estimated. And the same is true of the curative treatment of gonorrhea and puerperal septicemia. If both these conditions were treated early and vigorously, and if the treatment were continued for a long time, until the gonorrhea was cured, and the results of the puerperal sepsis removed so far as possible, there would be far fewer cases of chronic pelvic inflammation. Under the present methods of practice it is the disease which the gynecologist is called upon most frequently to treat.

4. *Lacerations due to Child-birth.*—Lacerations due to child-birth constitute an important class of the diseases of women. The relations of lacerations of the cervix uteri to sub-involution of the pelvic organs, especially of the womb, and to endometritis, has

been made known through the labors of American gynecologists, especially Dr. Emmet. For a time after the observations of Dr. Emmet were made public there was a tendency to magnify the importance of lacerations of the cervix, and succeeding that, a reactionary tendency to make light of the importance of this lesion, but the conclusion of the entire profession, based upon experience and common sense, practically supports Dr. Emmet in his original teachings concerning this lesion. It is not my purpose here to discuss the causes of lacerations of the cervix further than to say that my own experience is in accord with those who believe that many cases of lacerations of the cervix are directly due to the fact that the pregnancy has taken place in an imperfectly developed womb—the imperfect development being most marked in the cervix. Such a womb and cervix are not fitted to pass through the ordeal of labor unscarred. The cervix has to bear the brunt of the battle, and as a result of its imperfect development lacerates instead of dilating. This fact emphasizes the great importance of securing a full development of the womb.

Lacerations of the pelvic floor are of even more importance than lacerations of the cervix uteri. The giving way of the pelvic floor (the laceration of the levator ani and the pelvic fascia) is the foundation of almost every form of prolapse of the pelvic viscera. Cystocele, rectocele and prolapsus uteri are due almost without exception to lacerations of the pelvic floor.

5. *Miscellaneous Causes.*—Constipation plays an important rôle in the causation of some of the diseases of women. The fact that women very frequently suffer from constipation is well known. This is as true of young women as it is of their older sisters. Probably the principal reason for this is the in-door, rather inactive life which women lead; but an important factor is the habit which so many women form of having no regular time to have the bowels move. In this way the rectum is taught to tolerate the presence of feces which accumulate until the occurrence of headache, loss of appetite, malaise (symptoms of fecal absorption), force the patient to secure a stool, either by the use of an enema or by taking a purge. This over-filling of the rectum interferes with the pelvic circulation and in this way promotes congestion of the pelvic viscera. This habit predisposes to the development of hemorrhoids, also to uterine and ovarian congestion. It is usually assigned as one of the causes of retroversion of the womb, and of prolapse of the ovaries. I believe that it does predispose to both of these conditions. The full rectum can displace the cervix forward, and straining at stool, especially if the bladder chance to be full, can topple the womb over backward. Relaxation and loss of tone of the pelvic tissues, due to congestion, also predispose to retro-displacement of the womb and to prolapse of the ovaries.

Constipation aggravates the symptoms due to every variety of pelvic disease. This is brought about, partly by inducing pelvic congestion, and partly through the deterioration of the general health produced by fecal absorption and the contamination of the blood, and by the loss of appetite and disordered digestion.

ERRONEOUS HABITS OF LIVING.

Erroneous habits of living favor the development

of pelvic disease just as they favor the development of disease in other parts of the body. Pelvic disease may be produced, either by habits of indolence inducing a sluggish circulation and an atonic condition of the tissues, especially of the muscular system; or by habits of luxury, which usually involve the preceding, with the addition of irregular hours, more or less dissipation and the over-loading of the stomach with rich foods and wines; or on the other hand by too laborious and continuous work, over-taxing the strength of the individual, and by greatly increasing the intra-abdominal pressure, tending to displace downward the pelvic viscera—and in this way, at times, even in little girls, producing complete prolapse of the womb.

ERRORS IN DRESS.

Errors in dress is a subject of large importance, but it is only possible here to touch upon it. The principal error in woman's dress, as arranged at present, is, that by it the waist is unduly constricted. As this is brought about by means of the corset, which not only constricts the waist, but which also constitutes a brace confining the lower part of the chest, and also the abdomen, several results are induced. The first and perhaps the most important is the interference with respiration. It has been conclusively shown that the type of breathing of the female, normally, is the same as that of the male—diaphragmatic or abdominal, but owing to the pressure of the corset the excursions of the diaphragm are limited, and the same is true of the lower ribs and of the abdominal wall. The result is that the use of the corset has changed the type of woman's breathing to the costal, or really the upper costal. The principle of accommodation doubtless largely diminishes the interference with the normal circulation which this alteration in the normal type of breathing would otherwise produce. The second result of this method of dress is to make continuous pressure upon the abdominal vessels, and thus to interfere with the return circulation from the lower half of the body—promoting congestion in this region, which includes the pelvis. The third result is the displacement downward of the abdominal viscera, causing a protrusion of the lower anterior abdominal wall, and forcing the intestines down upon the pelvic viscera. In this way the displacement of the pelvic viscera is favored. The effect of the pressure of the corset upon the muscles of the middle portion of the trunk, and the support which the corset gives in holding the trunk upright (thus doing away with the necessity for muscular action in supporting the trunk), is to bring about the partial atrophy (or at least an atonic condition) of these muscles. The loss of normal tone in the abdominal muscles changes entirely the normal condition of intra-abdominal pressure, (favoring the displacement of the abdominal viscera), and takes away from the return circulation of blood in the abdomen one factor which normally is of great assistance in forcing the blood onward toward the heart.

Another error in the present mode of woman's dress is the manner in which the skirts are fastened to the body. This is by means of bands fastened about the waist. The effect of this method is that the entire weight of the skirts hangs upon the abdomen and hips. In women having a somewhat protuberant abdomen, practically the entire weight of

the skirts is supported by the abdomen. This adds to the intra-abdominal pressure and tends to force the contents of the abdomen into the pelvis. A further bad effect is that the waist band of the skirts compresses the trunk at the smallest part of the waist and adds to the ill effects of the pressure of the corset itself.

It has not been our purpose here to discuss the subject of practical methods of dress reform, but merely to point out the ill consequences of the present mode. The principles which underlie dress reform are: 1, that the waist shall not be unduly constricted so that the circulation and respiration shall not be impeded, 2, that the trunk shall not be encased in a brace, but that the muscles of the trunk shall be called upon to perform their normal function, which includes the sustaining of the trunk upon the pelvis and legs, and their proper part in the work of respiration, and in assisting in the return circulation of the blood, 3, that the weight of the clothing shall be supported upon the shoulders. These principles are unquestionably sound, and happily, methods of dress based upon them have been so perfected that at the present time women can dress in accordance therewith and not sacrifice either taste or beauty.

Practical Conclusions.—My object in presenting this paper is not to offer anything new, but to cover in a systematic way the causes of the diseases of women in order to show their limited character, and that these causes are principally of a preventable character. If I have succeeded in doing this, it follows that if proper attention were paid by the profession to the prevention of the causes which produce the diseases of women that these diseases could be very greatly restricted.

If proper attention were given to growing girls, especially about the time of puberty, and a more normal development of the sexual organs secured, if gonorrhea were more vigorously treated, and if the subjects of that disease were kept under observation until all abnormal discharges were arrested, and proper instruction concerning the abstinence from sexual intercourse were given; if antiseptic midwifery were faithfully and efficiently practiced; if lacerations of the cervix and perineum were early repaired, and if full instructions concerning the ill effects of constipation, improper dress and erroneous habits of living were given, the prevalence of the diseases peculiar to women would be very greatly restricted. I believe that this is to be the next great advance in diseases of women. Gynecologists must bring home to the general practitioner the fact that the diseases of women are largely preventable and make him feel his responsibilities, both as to their production after present methods of practice, and as to the possibilities of their prevention after improved methods. When the family physician realizes that it lies within his power very largely to prevent disease among the women of the families committed to his care, his sense of moral obligation will spur him on to do his full duty in this matter. When that day comes, the universal prevalence of disease among women will cease to be a reproach to preventive medicine.

Dr. HOWARD A. KELLY of Baltimore, congratulated Dr. Noble in bringing such an important subject before the Section in a new way. He had given the subject of preventive disease in women much thought, and believed a

book could well be written upon it. In many instances the cause of imperfect development of the genitals and of the general system was to be traced back of the child to the poorly nourished and ill condition of the mother before and after conception. Gonorrhea in children was not an uncommon first cause of disease in women. Tuberculosis had been found as the cause in one out of five of his operative cases of pelvic inflammation. We can not attribute too much importance to the accidents of labor.

Dr. HENRY P. NEWMAN of Chicago, said that prophylaxis should have its day, and he believed it would. When we consider such a paper as has been read, we can see how easy it is to institute prophylaxis and thus prevent a very large per cent. of prevalent diseases among women.

Dr. E. P. DAVIS of Philadelphia, said among the most intractable diseases of women was that of neuralgia—neuralgias not only dependent upon mal-nutrition or anemia, but especially those of the pelvic viscera as seen by the obstetrician and gynecologist. Methods of dress reform, the avoidance of constipation during the pregnant condition, as mentioned in the paper, would prevent a certain number of cases of severe pelvic neuralgia, notably those of the sciatic type.

Dr. JOSEPH PRICE of Philadelphia, had found vaginitis in infancy not an uncommon cause. Gonorrhea was now a frequent source of pelvic inflammation. In alluding to menstrual disorders, he was satisfied many of them began in infancy. The general attention of the profession to vulvular and vaginal discharges of infancy was neglected. Referring to the favorable statistics of some lying-in institutions regarding the mortality from puerperal sepsis, he said they did include the mortality from other causes. In an institution with which he was connected, not a child had been lost among 1,300 births.

Dr. C. R. REED of Middleport, Ohio, thought that an infantile uterus was probably one of the most important causes of illness and feebleness in the women of our country; that deranged or vicious menstruation grew out of imperfectly developed sexual organs. The most difficult cases he had to manage and which gave him the least satisfaction and benefit to the patient, were in those young women who had undeveloped uteri and ovaries. The doctor made a mistake in telling the mother it would be all right after marriage; for unless measures were taken for better development, the marriage would be sterile—the patient would suffer.

Dr. J. HENRY CARSTENS of Detroit, Mich., did not believe that gonorrhea was so common a cause of pelvic inflammation as some practitioners. He thought a more frequent cause for the troubles in some women was the vicious habit of producing abortion, resulting in chronic inflammation of the uterus, and was a cause of more pelvic inflammation than all of the other causes put together. The profession should endeavor to prevent the vicious habit of women producing abortion with dirty darning needles, etc.

Dr. J. W. HOFF of Pomeroy, Ohio, desired to enter his protest against the statement of so many girls having had gonorrhea. He had practiced for forty-seven years, and had not seen half a dozen cases in daughters. Perhaps it was not so common as it had been represented in Philadelphia.

Dr. JOSEPH HOFFMAN of Philadelphia, directed attention to affections of the bladder incidental to parturition and to the puerperal state, brought on by constipation and dislocation of the uterus, etc. Of all the troubles women were heir to, chronic cystitis was the one with which they are most frequently affected. He thought that many of the troubles with which women are afflicted, such as displacements, retroflexions, subinvolution, etc., could be avoided by insisting that the patient remain in bed for two weeks

after child-bearing. As to the occurrence of gonorrhea in children, he had rarely seen it. He had often found tuberculosis in the pelvis, and he believed it frequently followed pus collections, if it was not caused thereby.

Dr. E. H. N. SELL of New York city, had seen gonorrhea in children, and even in a minister's family from a supposed moral country district. He would not mention the State. In one case the disease extended so as to involve both bladder and kidney.

Dr. LEWIS S. McMURTRY of Louisville, Ky., said it had been demonstrated by modern pelvic surgeons beyond question, that the physician in his efforts to relieve functional disorders of the pelvic organs in women very often unnecessarily inflicts upon them a disease of far more gravity than the one to which his treatment is directed. To illustrate: There is not an operator present who has not seen intra-pelvic inflammation result from forcible dilatation of the cervix. He is also perfectly satisfied that serious tubercular diseases are the result of the routine use of caustics upon the cervix—a practice still in vogue by some practitioners.

Dr. NOBLE, in closing, said he felt satisfied he had met with tuberculosis in several of his cases, as mentioned by the preceding speakers, although no microscopical examinations had been made. With reference to the relation of imperfect development of the uterus to the accidents of labor, he does not wish to be understood as saying that all lacerations of the cervix are due to this condition. In many cases they are due to bad obstetrics. The cause of a good deal of mischief is a very large baby coming through a small pelvis.

A FEW POINTS OF INTEREST TO THE FAMILY PHYSICIAN.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY JOSEPH EASTMAN, M.D., LL.D.
INDIANAPOLIS, IND.

It is more or less presumptuous for a specialist to attempt to teach the general practitioner for two reasons: First, a large per cent. of general practitioners are capable of furnishing more pointers to the specialist than he could use in his business than the specialist could furnish to the general practitioner. Secondly, so many epistles have come from gynecological apostles in the past few years intended for the edification and education of the general practitioner that the man who makes his living by doing family practice is beginning to seriously reflect upon what relation he bears to the specialist.

Had I not for fifteen years been actively engaged in general surgery and medicine, nothing could have induced me to place my foot in this field which is actually suffering from intense cultivation, but now that specialists in gynecic surgery are starting up in almost every county seat I think it might be well to "tap the wheels" and elicit, if possible, the ring of solid metal or perchance the dull sound which indicates a crack in the wheel of our rapidly moving train.

Those of us who have opened the abdominal cavity many hundred times and tested our asepsis in the great lymph sac have picked up many little points pertaining to aseptic and antiseptic precautions of much value to the general practitioner. He has, however, often been led to believe that there are two separate and distinct factions; the one contending for and the other against antiseptics. There are no differences. "All are but parts of one stupen-

dous whole." Therefore he has the right to throw the blame on the eclecticism for his having committed a sin of omission, not using enough soap and water; or a sin of commission, having depended too exclusively on his bichloride solution and failed to scrub (sterilize) his hands, and even poisoned his patient with the deadly drug. The greater our experience and the more marked our success, the keener we should feel the weight of responsibility resting on us for what we teach. Reckless expressions as to methods of operating, treatment of cases, or results obtained are most reprehensible, even criminal, for in this way lives are sacrificed.

The student of human nature and the earnest seeker after truth can see the motives of those who insist that any kind of water is as good in surgical cleanliness as that which has been sterilized, or teach in their published statements and attempt to prove by their success that private hospitals are useless; that the same success can be obtained in the fifth hovels of the city; that nurses who have had a large experience in supplementing the efforts of the abdominal surgeon with their wisdom obtained by observation are no better than such nurses as one can pick up. What is the difference, if in the use of chemical agents which destroy microorganisms, we advance a step farther and say prevention is better than cure; or that the prevention of fermentation—"sterilization," "asepsis," "clean surgery" are better than allowing fermentation and putrefaction to swarm with microbes, and then seek to kill them with chemic agents?

There is no difference in the ultimate aim of those contending for antiseptic surgery, and those who claim to be content with clean surgery, for the reason that cleanliness can not be secured and maintained without the aid of chemic agents of some kind. No wonder some of our surgical friends get blinded in the technique of antiseptic surgery. While wandering in their blindness they forget the principles enunciated by the great masters like Lister and Keith. These men proved by scientific research that all fermentation is molecular life. What use would there be in the sterilization of every instrument used in the pelvic abscess if we forget that pus cavities, after being exposed to the air, become a hot-bed for the production of germ life through fermentation and putrefaction? Of what use would all the antiseptic dressing over an abscess be, as compared with perfect drainage—that precious safeguard against absorption? Our apostles of clean surgery are exceeding careful as to who clean their sponges; do not allow any decaying organic substance in their private hospitals, knowing that no sooner does one decaying substance die than it begins to live again in molecular germ life, the prolific offspring of fermentation and putrefaction. Clean surgery is what we want. How shall we obtain it? By water? No; it can not be thus secured. Suppose one of these gentlemen drops blood, pus or serum on his clothing, or gravy on the lapel of his coat. Will water remove it? No; try soap, ammonia, ether, benzine. Ah, it takes chemicals to secure cleanliness. The difference between those favoring and those opposed to antiseptics is largely imaginary, a play on words. We can get it but not without the aid of chemicals. By this, I do not mean such agents as are usually considered germicides. I doubt the propriety of killing germs lest we irritate the tissues. These

pretended differences between sepsis and antiseptics can but confuse the average general practitioner or the beginner in surgery. For example: My friend who had located in the far west and had been doing some surgery, returned to make his friends a visit; found his way up to my operating room and was noticing our preparations for work. As I had once been his teacher I began answering his questions by explaining to him that the hands were the most frequent source of conveying septic material into the peritoneal cavity, and that for the past ten years I had been studying how to clean my hands; that now I had a soap made by a chemist, with olive oil and caustic potash, practically the green soap of the pharmacopeia. I showed him my scrub brush for the hands which is boiled every time after being used and then kept in alcohol and ready for use again.

I explained how it takes repeated rinsings to get rid of the soap suds from the pores of the skin before we place the hands within the abdomen. He answered me, "I have no use for all your details. I simply put my hands in the solution of bichloride of mercury and then I know that I am safe." I attempted to reason with him, stating that if I used a germicide for the hands it would be aqua ammonia, which would not only bring tears to the eyes commensurate to the solemnity of the occasion, but would penetrate deeply into the pores of the skin chasing the microbe home, and by its extreme alkalinity, if not killing him outright, weakening him until he would be comparatively harmless. Whereas, his bichloride of mercury by its astringency, would close the pores of the skin, thereby shutting the door after the microbe which it had frightened into its den. This doctor believed that there were two factions and had chosen the chemist side of the question.

I read in a medical journal an article by one evidently willing to teach the average doctor. In this article he describes the bleaching method much used in the Johns Hopkins hospital and other places. He says: "Making the hands brown in a solution of permanganate of potash, then immersing them in a solution of oxalic acid until the color of the potash is removed; the hands will be of a pink color." Here it is that "a little knowledge is a dangerous thing." The pink color is evidence that the acid is retained deeply in the pores of the skin of the hands, even after repeated rinsings under a stream of running water. Such hands put into the peritoneal cavity would be dangerous. Aqua ammonia applied freely will prove the presence of acid by making as much lather as could be made with a good article of soap. This repeated a few times the pink color is gone and the hands are anemic. This alternate flushing and shrinkage of the capillaries, making the pink color, no doubt helps to sterilize the hands. It could be as well done by alternately immersing the hands in cold and hot water.

Another friend asks me to meet him in consultation, his patient having been confined a few weeks before. He fears peritonitis and yet thinks it not possible, as the temperature has not been above 101, though the pulse is 140, wiry and feeble. The abdomen is badly distended. The pulse, the tongue and the countenance all point to septic peritonitis and death. Following the doctor I made a careful examination of the case. I asked for some soap and water to wash my hands. They furnished a piece of soap

which had probably been selected, not because of its known composition, but because of its recommendation in the newspapers, including a certificate from a Brooklyn minister. The water given me was hard, containing much lime, magnesia, etc. I whispered to my friend that I could not remove septic germs from my hands with such material. He immediately brought his satchel, and after handling nearly everything in it gave me some tablets of bichloride of mercury to put in the water, and thereby to increase the chemical composition of the water and render it more worthless in cleansing hands.

After handling everything in his satchel he washed his hands in a solution of bichloride. Now, had he carried a hand brush boiled every time it had been in doubtful use, a vial of aqua ammonia to soften the water and a piece of soap made of olive oil and caustic potash, imitating the time honored soft soap of his grandmother, his armamentarium for sterilizing hands would have been nearer to my notion. There is something in soap. I ask the man in the alley back of my stable what he is going to do with the putrefactive, maggoty carcass of a dead dog he has laid in his cart. His answer was that he hauled them to the soap factory. I repeat there is something in soap. I insist there was a good deal in that soap. The nearer we stick to the religion and soap of our grandmothers the nearer we will approach moral and physical cleanliness of body and mind.

This good doctor was deceived as to the disease by too implicit reliance in his thermometer. I have many times seen a patient with septic peritonitis lie down and die, while I have never known a pulse to deceive me. We had in the profession more good pulse feelers before we had so many thermometers.

I get into my friend's buggy to ride home. He buttons up two coats, strokes down his long full beard, with hands and sleeves teeming, as I believe, with germs of septic peritonitis, then puts on a heavy pair of warm driving gloves which had done him service two winters, surely nothing but fire could ever sterilize them. Five days later my good friend rushed into my operating room as we were getting ready for an abdominal section waving these same driving gloves in his hands. I asked him to retire. He did so, but remarked that he had changed his clothes.

This doctor's antiseptic precautions were faulty because of too implicit reliance in germicides which led him to overlook the fact that any microbe, having a particle of self-respect, would not attempt to stay where soft water, clean scrub brushes, plenty of elbow grease and repeated changes of clothing were customary.

The doctor's change of clothes was not satisfactory to me, so long as the gloves were used into which he had placed his hands after examining the case of puerperal septicemia. It requires the utmost painstaking to have our chain of antiseptic precautions strong in its entirety. "No chain is stronger than its weakest link." In studying septic precautions and applying the principles in our practice we often strain at a gnat and swallow a camel. This being true of those who are specially engaged in intra-peritoneal work so that the least deviation from the strictest asepsis will be detected in the results obtained, how much more likely is he who is engaged

in general work to overlook some important detail in the change of clothing, and especially in what he is handling with his hands, including the gloves.

It was taught in former years that the obstetrician should stop practice after attending a case of epidemic child-bed fever.

These cases we now believe to have been puerperal septicemia, and despite my unbounded confidence in soft water, soft soap, scrub brush, ammonia, turpentine and alcohol, I am of opinion that no man is warranted in opening the abdominal cavity or attending an obstetric case within five days after his hands have been in contact with a case of septic peritonitis, if that peritonitis is at all in any possibility during its acute stage; and not even after the expiration of five days unless in this space of time there shall have been repeated changes of clothing, daily scrubbing of the hands and arms with soft soap, soft water, with ammonia poured into the brush and the hands immersed in turpentine afterwards. In this purification the hair and beard should receive due attention.

This statement may be challenged by those who make abdominal sections in cases of pus tubes, but I must draw the line between cases of sub-acute and acute septic peritonitis whether the same be puerperal or not. In a recent conversation with Dudley of Chicago, I find that this conscientious man has been thinking in the same line and arrived at the same conclusions as myself in this regard. Have we not erred in publishing to the general practitioner what numerous lives we could save by abdominal surgery? Would it not be better to give him the benefit of our experience and some of the details of our aseptic precautions, and thereby enable him to avert the probability of carrying the death warrant of his patients in the hair follicles on his hands, under the finger nails and in the gloves? Is it not time that we quit contending that there are two factions in antiseptic surgery, one depending on water, the other on chemicals? Inasmuch as chemicals are useless without water and water without chemicals, even a soap of known chemical composition, the systematic combination of the two in the proper way of their use upon the hands is what the average physician needs to know. The man who is daily dealing with the peritoneal cavity has a store of knowledge of great utility to the general practitioner. And yet we must forget self and publish only that which we have proven to be right and safe, like Dr. Kelley who discarded the *American Journal of Obstetrics* when he found that his bleaching solution of potash would not kill bacteria in a skein of silk.

I meet my friend in consultation. He had told me to bring all kinds of probes to get entrance into the cervical canal as he had failed to find an entrance into the uterus, notwithstanding he had used the speculum many times. I found the uterus crowded up behind the pubes by an ovarian cyst as large as a water bucket which the doctor had not detected; secured the consent of the patient and set the day to remove the cyst. As we were about to leave, the doctor asked if I had not better use the speculum to see if we could not pass a sound. I replied that fingers were made before forks, speculums or sounds and that conjoined manipulation gave so much information that sounds were going out of use. A very large majority of practitioners I meet are capable diagnosticians. A few are sadly

deficient in physical diagnosis of abdominal disease. It is often a lack of persistence in abdominal palpation and determination to master the subject. They have not the art of moving the fingers over the viscera carrying the skin with fingers. And sometimes they do not even obtain a knowledge as to whether the tumor grew from above downwards or from below upwards. If from above downwards, can it be manipulated back, as in floating kidney, or moved from side to side, not upward, as in distended gall bladder. They do not understand that palpation of an ovarian cyst should give signs of fluctuation, and a fibroid of a solid; that in both there would be dullness on percussion. Whereas, in ascites there would be resonance. I mention these points because there is some danger of inspection, palpation, auscultation and percussion becoming a lost art. There are so many anxious to make exploratory abdominal section.

One of the ablest practitioners of my State calls me in consultation. His telegram suggests that I come prepared to make an abdominal section. The case is a boy and he has been suffering three days from inflammation with excruciating pain in the region of the vermiform appendix. The doctor has made post-mortem examination, finding a gangrenous vermiform appendix, and from his knowledge gained by this post-mortem and by his reading the current literature of the day, especially the teaching of Morris of New York, that all cases of appendicitis should be operated upon, believed that success would follow and life be saved if we only operated early enough. I, having seen a few operations followed by death because the inflammation was yet in an acute stage, that is to say while the circumscribed septic peritonitis, which sometimes accompanies cecitis and appendicitis was acute not sub-acute, believed that an operation would surely be followed by death, and that if by opiates we could arrest the progress of inflammation and seize the opportunity in the interval of the attack, operative interference might do some good. Knowing also that some of these cases make fairly good recoveries without operation I declined to operate. Neither the doctor nor myself were satisfied with the result in this case, and this subject is of such vital interest to the general practitioner that I quote from a recent article by Dr. Schaefer as being in point: "It has been asserted by McBurney of New York, that 90 per cent. of all cases called perityphlitis are really cases of appendicitis, and this statement seems to have been almost universally accepted by the profession of our country, for the term perityphlitis has been almost entirely dropped from the textbooks and the writings of most surgeons, and appendicitis adopted as a substitute. This change of terms has been accepted with too great haste in our judgment and is in all probability one of the chief causes which lead to the great differences of opinion relative to the question of operating; for we shall find upon searching the literature of this subject that various conditions may be and in all probability are described under the term 'appendicitis.' I am led to believe through my experience that a larger percentage of cases of so-called appendicitis than we are aware of are inaccurately diagnosed. This, of course, will be difficult to prove, but when we look at the facts produced by practical experience, enough presumptive evidence can be brought forward to indicate that the assertion

is not without foundation. How do we arrive at the facts concerning the statistics of appendicitis? 1, by noting operation. 2, by recording results of autopsies. But is it not reasonable to suppose that the greatest source for statistics for lesser diseases of the caput coli is lost in the fact that they recover (it is claimed by Treves that 90 per cent. of all cases get well spontaneously) so that no autopsies are made? I feel convinced that a simple catarrhal enteritis with an accumulation of fecal matter, is mistaken for appendicitis much more frequently than is generally conjectured, having had at least five cases of this kind recently myself which recovered. In each, after the acute symptoms were subdued, repeated colonic flushing brought away large quantities of dry, lumpy, fecal matter and the tumor vanished. In considering this subject we are at once confronted by two problems: 1, diagnosis. 2, the question of operation. In perusing the literature of perityphlitis and appendicitis which during the past few years has become extraordinarily voluminous, one is struck with the fact that most writers and operators take a radical stand for or against operative procedure, and those who favor operating are again divided upon the issue of 'early or late' operations. It seems strange to the casual reader that minds experienced in the same line of work should differ to so great an extent in considering questions of so practical a nature. There is an old axiom, 'whenever pus is discovered let it out if possible.' That the indications for the evacuation of pus in this instance are of greater import than in any other conditions or locations no one will dispute. What, then, causes the hesitation? 1, the difficulty lies in finding the pus. 2, the great danger to the peritoneum and its sequelae. The first difficulty the surgeon will always be confronted with in a proportion of the cases. The second difficulty will be more and ignored as we become more familiar with the work, and more perfect in antiseptic surgery."

Here is common ground where a wise general practitioner with large experience and much reading meets the specialist, both determined to do the very best thing for the patient, and yet they can not see alike.

Between the general practitioner and the specialist; the one looks at the thing in a general way and the other in a special way. They are both instructed by association together over a given case. The ideas of the specialist are widened. The ideas of the general practitioner are narrowed to a closer study as to the particular stage of the disease suitable for operative interference; and ultimately we shall, as I believe, unite in a mutual faith that when to operate is a vital question requiring much skill and surgical wisdom to answer, and even then we will sometimes find that our best judgment and conscientious actions have failed to save a life. I believe that the specialist should concede much to the experience and judgment of the general practitioner. What success I have had is in a measure due to association with successful, intelligent, general practitioners. I believe the specialist should be as a hand maid to the family physician, by no means supplanting her mistress nor yet usurping her rights but always assisting her to maintain them.

THE RIGID OS AS A COMPLICATION IN LABOR.

Read before the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY E. H. KING, M.D.
MUSCATINE, IOWA.

One of the most frequent complications which occurs to annoy the obstetrician, protract labor and exhaust the patience and endurance of the parturient, is a rigid and unyielding os.

This term is applied in a general way to a variety of conditions, materially differing from each other; but possessing this feature in common—the cervical tissues are unyielding, and the os undilatable.

This may depend upon non-development in the early primipara; upon fibrous degeneration in the old; upon cicatricial induration, consequent to previous lacerations, and upon pathological change, incident to carcinomatous disease.

But we frequently find a persistent rigidity where none of these conditions are present; wherein the lower uterine segment is apparently fully developed, and normal in character, thin and soft when quiescent, but upon the advent of each uterine contraction the encircling tissues spasmodically contract and become rigid and unyielding. More or less sensitiveness and irritability of the cervical tissues are present, and occasionally we find an acute hyperæsthetic sensitiveness of the whole vagina, sometimes accompanied by local heat and dryness. The patient is restless, nervous, irritable and depressed, is annoyed by examinations, suffers severely at each recurrence of uterine effort, and persistently demands relief from the attendant.

Again, we may find the encircling tissues to be a thick muscular band, insensitive and rigid.

The patient may be in good health; presentation, position, the relative size of the child to the maternal pelvis, uterine contractions and personal effort may be all that could be desired, yet, whenever these rigid conditions persist labor will be correspondingly protracted, the patient subjected to increased and unnecessary pain and distress and liable to suffer from injurious sequelae.

The most serious, but fortunately the least frequent result to be apprehended is rupture of the body of the uterus, allowing its contents to escape into the abdominal cavity. More frequently has there been a complete separation of the cervical rim, and quite frequently, or rather perhaps, the usual result is more or less laceration of the cervix, giving rise to hemorrhage and laying the foundation for future pathological and gynecological conditions, which afford a fertile field for the specialist to cultivate, often to his own financial rather than to his patient's physical improvement. Unaided, after long continued and vigorous efforts, the minor tissues around the os may tire out and give way to slow dilatation; but more frequently the sudden rupture or laceration, previously noted, may occur, and labor be advanced towards completion. Then, too, long continued pressure against the cervical rim, especially in the absence of the protecting bag of waters, is liable to cause confusion with subsequent necrosis, which will add another factor towards future pathological complications, and trouble and ill health for the patient.

In cases wherein structural change has occurred from carcinomatous deposit, surgical interference is beyond doubt the proper method of relief; making lateral or bi-lateral incisions through the diseased tissues and keeping the patient sufficiently anesthetized to prevent undue suffering until delivery is accomplished. Incision is also proper in cases of non-development, and in fibroid degeneration after failure to obtain dilatation by milder means.

In cases of irritable, spasmodic or of muscular rigidity, various methods and remedies have been employed. Blood letting to faintness is an old remedy and often effective; but bleeding is not fashionable at the present day, and the average practitioner does not possess the necessary moral courage to revive the practice. The relaxing effect of the hot bath, recumbent or sitz, has been used with benefit, but is often inconvenient or impossible to give in general practice. Ipecac, tartar emetic, lobelia, tobacco and other emetics have been given ad nauseum with more or less effect, but more often to the doctor's disappointment, and the patient's disgust.

Digital and instrumental dilatation has its advocates, but is objected to by those who live in mortal dread of any such interference, on the score of the danger from septic infection. Chloral hydrate is often used but is perhaps of more value to relieve the excessive irritability and procure rest than to effect immediate dilatation, and the same may be said of opiates in their various forms.

Undoubtedly the most popular remedy of recent times is anesthesia pushed to a degree of complete relaxation. It is often efficient, and as it relieves the patient from the agony, it is hailed with delight by the sufferer and ever after held as a boon of inestimable value. But anesthesia will sometimes fail and organic disease or personal prejudice may preclude its use.

I have the pleasure to offer another remedy, not to my knowledge generally used by the profession for this purpose, viz., atropia used hypodermatically. So far as I am aware, it was first used for this purpose by the late Dr. A. Ady of West Liberty, Iowa. Although belladonna extract and ointment has been applied to the cervix for this purpose from time immemorial, Dr. Ady has used atropia for many years in his practice, and he states "that it will as certainly dilate the os, as it will the iris," and in the cases wherein I have used it, I can fully concur in the statement. I believe it to be the most prompt and efficient remedy we possess to inhibit the contractility of the circular fibers of the cervix, thereby favoring prompt dilatation and thus accelerating labor. 1-100 gr. will generally be sufficient. Its effects will be manifest in from fifteen to twenty minutes. Rarely will a second dose be necessary.

The only unpleasant symptom attending its use is the dryness of the mouth and fauces and dilatation of the pupils. Neither in Dr. Ady's experience or in my own has it seemed to favor hemorrhage or interfered with postpartum contractility of the uterus or with lactation.

Possibly, delirious excitement may be caused by it in persons peculiarly susceptible to such an effect of the drug, but such cases must be extremely rare.

I therefore briefly present this remedy to the profession that it may be given a thorough and satisfactory trial, and its true value be determined.

EPITHELIOMA OF THE TONGUE, AND ITS TREATMENT.

[Abstract of a paper read before the Society of the American Medical Association, at its annual meeting, 1892.]

BY L. C. LANE, A.M., M.D., BERKELEY, CALIF.,
PROF. IN THE COLLEGE OF MEDICAL SURGERY, SAN FRANCISCO, CALIF.

The author of this paper accepts the view of these observers who assert that epithelioma is the only form of malignant neoplasm which attacks the tongue, except such as may have reached that organ after primary invasion of contiguous structures.

Epithelioma has its origin deep in the epithelial elements and, according to its site, may be divided into two classes—the excrecent, and the internal or interstitial. Each form may arise from a papilla, wart, naevus or limited abrasion. In the excrecent variety the growth is outward, tuberculated or wart-like prominences being isolated or forced into an uplifted plateau. The penetrating species commences usually on the side of the tongue, the newly formed elements crowding upon and destroying as they invade, the deeper structures, finally reaching and opening blood vessels of more or less magnitude. These metastatic processes are continued until the affection has no definite bounds.

The causation of epithelial cancer of the tongue is unknown, but certain agencies might be cited as promoting its evolution, such as calcareous incrustations on the inner side of the teeth, sharp points or edges of the teeth which continue to wound the borders of the tongue, and the habit of thrusting the tongue into an interstice between the teeth. The use of tobacco is probably a causal agency, the disease being far more frequent in men than in women. Epithelioma of the tongue seldom appears before the fortieth year of age. When allowed to run its course lingual cancer completes its fatal work within fourteen months. Operative interference does not offer encouraging prospects because so frequently undertaken late in the progress of the growth. Probably as high as 75 per cent. of the cases might be saved if the disease were seen in the primary stage and treated upon surgical bases, but meddlesome ignorance too often monopolizes the precious time during which the patient might be saved. The absence of metastatic glandular infection may be regarded as the only test of safety. When intelligent management has stepped in and prolonged life, two years is usually the limit of time, before death ensues.

The author's paper considers at length the gross pathology, diagnosis and surgical treatment of lingual epitheliomatous growths and contains ample bibliographical research with citation of cases.

MUSCLE BUILDING AS ILLUSTRATED BY THE MODERN SAMSON, SANDOW.

BY G. FRANK LYDSTON, M.D.

PROFESSOR OF THE SURGICAL DISEASES OF THE GENITOURINARY ORGANS AND SYPHILOLOGY, CHICAGO COLLEGE OF PHYSICIANS AND SURGEONS, ATTENDING SURGEON, COOK COUNTY HOSPITAL.

It has frequently been remarked that men of the present day are not so strong as those of times past, and there are many reasons for this assertion. An inspection of ancient armor is sufficient to convince one of the truth of this statement. In looking at specimens of ancient armor, we are at once impressed with their great weight and comparatively small size,

It would distress John L. Sullivan, I have no doubt, to force himself into one of the largest suits of armor that have thus far been exhibited. Once he had succeeded in arraying himself in the suit, he would doubtless feel more like reposing peacefully upon the ground than vaulting into a saddle and running a tilt in a tourney. One thing is certain, viz: that the soldier of ancient times although by no means a Sullivan in physique, could put the average modern athlete to the blush in point of strength and physical endurance. It is obvious that the men of former days must have made up in the quality of their muscular fiber what they lacked in bulk.

Of all the living modern examples of muscular possibilities Sandow is probably the finest specimen.

axilla and over the shoulder, 21 inches. The maximum chest expansion is said to be 14 inches.

I have not had the opportunity of verifying these measurements and am inclined to believe that they are somewhat exaggerated. Especially am I inclined to doubt the chest expansion, which although simply wonderful would, I think, show somewhat differently from the published estimates.

To the student of anatomy Sandow is an object lesson worthy of study; a more beautiful demonstration of the superficial and more important muscles than this man presents could hardly be imagined. This demonstration is made possible by the perfect control which Sandow possesses over even those muscles which, however excellent the natural development of the individual, are never under very perfect volitional control in the average subject. In an experience and observation of physical training and its results, extending over a period of twenty years, the writer has never seen an athlete who has attained a degree of perfection in this respect which could be compared with that attained by Sandow. A glance at the pictures which have been reproduced from the photographs which Mr. Sandow kindly presented me, will well illustrate some of the points in his development which are most noteworthy. It has often been said by scientific iconoclasts, that ancient painting and sculpture is very unreliable in anatomical details. Especial stress has been laid upon the "checkerboard" appearance of the abdomen seen in various heroic works of art by the old masters, as an illustration of this defect. If the reader will glance at the front view of Sandow, he will observe a division of the abdomen into rectangular areas of muscular eminences which are more prominent than those of any painting or statue with which I am familiar. This extraordinary development of the recti is, however, by no means disproportionate to the development of the other muscles of this remarkable man. On inspecting the back, as seen in the cut, a clear, distinct outline of the various muscles is observed. Attention is especially directed to the scapular muscles and the trapezii. The muscles of the limbs are equally well developed. The pectorals and that usually poorly developed muscle, the *serratus magnus*, are of phenomenal development.

When at rest, Sandow's muscles and skin are soft and pliable, but when the muscles are contracted from voluntary effort, it is wellnigh impossible to pinch up the superlying tissues.

It is a striking fact that Sandow belongs to a family no other member of which was ever noted for great strength; or, even a taste for athletics. Sandow himself, until he was 18 years of age, was of rather frail build. At that age he began a systematic course of training by a method peculiarly his own. His system consisted essentially in the acquirement of perfect voluntary control over the various groups of muscles, and where possible of single muscles. By thus specializing he was enabled to localize his muscle building where it appeared to him to be most needed. Having acquired a fair degree of development and control of the group selected, he then devoted his attention to another, and so on until he had succeeded in acquiring the foundation of the remarkable general development which he now presents. According to Sandow, the only apparatus used in his preliminary training was a pair of five pound dumb bells. It was not until he had attained

This man shows in a very marked degree the wonderful results which can be obtained by a systematic and philosophical method of muscle building. Sandow is by no means a large man, being but 5 feet 8½ inches in height. To see him arrayed in evening dress, the uninitiated would hardly believe the tales of physical prowess which can be told of Sandow, and he was born in Prussia, and is now 26 years of age. He weighs—stripped to the buff—186 pounds. The measurements which he claims are: Chest, 46 inches; waist, 29 inches; biceps, 19½ inches; thigh, 21 inches; forearm, 19 inches; calf, 17½ inches; under axilla and over deltoid, 17 inches; under

an approximately perfect general development that he began those wonderful feats of strength which are now his daily avocation. To those who have not seen him at work, Sandow's exploits sound like a fairy tale. He plays with fifty-six pound dumb bells as though they were marbles, and with eyes blind-folded, his feet tied together and one of these heavy bells in each hand, turns a back somers-aunt as gracefully as could any empty-handed gymnast. After this preliminary warming up, a huge dumb bell, each end of which is formed by a hollow globe containing a man, is brought in, and our modern Hercules gracefully lifts it from the floor and pushes it straight up with one hand at full arm's length above his head

with apparent ease, letting his burden down again without shaking up his living dumb bell to any great extent. The weight of this bell and its contents is 305 pounds.

A still more wonderful feat is his exhibition on the Roman column. Strapping his feet to an iron upright at some distance above the floor, he supports his weight by a couple of straps attached to his knees. Leaning down backward from his horizontally extended position he then picks up two men, one after the other, and places them upon his knees. The strain upon the back, thighs and arms in this feat can be readily imagined. As a climax for his

exhibition Sandow next supports a platform upon his chest and knees while resting upon his feet and hands, and upon this platform three trained horses are balanced. The combined weight of the platform and horses is about 2,800 pounds.

Much curiosity has been exhibited regarding Sandow's system of training, especially as regards his diet and mode of life. It is not worthy that he eat, drink and smokes about as he pleases, the old fashioned idea of dietetic restriction for athletes evidently having very little weight with him. It is astonishing that he is not compelled to be more abstemious, but he is apparently quite as capable of immense muscular effort after a course dinner and a liberal supply of wine, followed by one or more cigars, as at any other time. After his performance is ended Sandow takes a cold sponge bath and a rub, as does every well informed athlete.

According to Sandow, ten minutes exercise with five pound bells night and morning is all that is necessary to attain a superb muscular development. In proof of this, he exhibits a pupil in whom three months training has produced marvelous results.

Irrespective of my own opinion regarding the disastrous effects of such severe strains as those imposed by Sandow upon himself, I am compelled to confess that I have rarely examined so perfect a type of good health as this man presents.

A heart perfectly normal in size and action, and lungs free from emphysema, are hardly to be expected in one whose daily work comprises such a series of severe muscular strains as those to which Sandow subjects himself, yet these organs are apparently sound. The heart is not disproportionately developed and its action is perfectly normal. Even under severe strain the respiration and heart's action are but little disturbed. I found that the respiratory movements numbered 20 per minute and the pulse 80 before our subject went upon the stage. On examination about half an hour after the regular performance—during which time Sandow occupied himself in displaying his muscular development to a select audience in his dressing room,—the pulse was 90 and the respiration 20. It is worthy of remark that he had partaken of a hearty meal with a liberal supply of champagne shortly before the performance and had been smoking freely during the evening. The average athlete would hardly dare to go through such preliminaries even when ordinary feats were to be attempted. By far the most interesting feature in Sandow's work is his method of muscle building. He begins as already remarked, by cultivating volitional control over the several muscular groups. This is especially interesting to me as it is precisely the same system that I have advocated in several articles upon physical training, and is essentially the same as that which I put in practice in gymnastic classes some years ago. The principle involved in proper muscular training is exemplified by those individuals who by practice are enabled to acquire great volitional control over such muscles as the articular and occipito frontalis. As is well known, the platysma myoides is poorly developed in the human subject, being but a remnant of the panniculus carnosus. It will be found that it is possible to acquire a marked degree of development and control of this thin and unimportant sheet of muscular fibers. If this can be accomplished in such muscles as those mentioned, it is certainly reasonable to suppose that more per-

fect results can be accomplished in the case of the more important muscular groups. By systematic practice in this direction one is enabled to get sufficient exercise without any apparatus whatever. It is the relative degree of control which the individual acquires over his various muscles, rather than their bulk, that determines their strength. Such enormous development as that of Sandow, is by no means necessary nor even advisable. Feats of strength do not constitute the aim of ideal athletics, i.e., athletics for health. Given a bulky muscle, and we usually have a slow muscle. The ideal muscle is not always the one which stands out in such bold relief as do those of Sandow. The average big muscled man is muscle bound, and perhaps shoulder bound, and while Sandow is apparently an exception to the rule, he himself in all probability displays to less advantage in feats requiring a combination of skill, strength and agility. The question is often asked of Sandow, "what could you accomplish in pugilism?" Sandow replies and quite justifiably that he would not dare strike a man; that he can break a four inch plank with a blow of his fist, etc., but the ability to kill a man with a blow of the fist is not pugilism, and striking a plank is vastly different from striking an active skilful boxer, who is not in duty bound to stand still and be struck. Very few boxers are ever able to exercise their utmost strength in striking a blow. To put a blow accurately and quickly in upon an object in motion, is vastly different from striking a sandbag. Especially is this true when the danger to one's self is proportionate to the violence of the attempt made in striking an opponent in case a counter blow is received. Experience has shown that bulky muscled men are, on the average, failures as pugilists and wrestlers. Corbett is an ideal athlete, yet his muscles are smooth, well laid and not bulky. It is to be hoped that Sandow's exhibitions may not have a pernicious effect upon aspiring youths who imagine that ideal training implies great feats of strength, and muscles which stand out in bold relief like an anatomical demonstration.

A point worthy of consideration is the fact that Sandow is of a very phlegmatic temperament. Persons of a more sensitive organization, and brain workers, would soon pass the danger line if they attempted to emulate Sandow. The personal equation must be remembered in athletics as well as elsewhere. A word of caution is also necessary in respect to diet and drink. While a restricted regimen is a relic of the past in athletics, more care is necessary than Sandow imposes upon himself—the personal equation again. Wine, tobacco and athletics mix but poorly.

The question now arises: what damage if any, does such work as Sandow's produce upon the individual? From what has been said of Sandow's present condition one might be led to infer that such feats of strength are harmless, but such is not the fact. Sandow is confronted by two dangers. 1st. Death at an early period after complete suspension of his athletic strain. 2nd. Death at middle age or soon thereafter, from a continuance of his work.

In the first instance we will suppose that our subject ceases his work—voluntarily or otherwise. In this event he is confronted by a serious problem. He has solved the problem of developing his heart and lungs *pari passu* with the development of his general muscular system, but how is he going to

bring about involution of his lungs and heart *pari passu* with the general muscular involution which must follow rest? To do this is impossible and the result is a relative disease of his enormous heart and lungs. Disuse means decay; degeneracy of cardiac fiber and lung tissue results; degeneracy offers a constant invitation to disease of various kinds. The most powerful pugilist America ever produced, quit the "squared circle" and entered a counting room, only to die of consumption within a year. The athlete had need of large lungs, but large lungs without their accustomed exercise were a misfit in a sedentary occupation.

We must not forget in considering the immediate effects of muscular strain, the possibility of chronic myocarditis. Many a powerful man has paid the penalty of over exertion by the development of so-called heart failure during some acute disease. I recall the case of a professional friend who used to boast that he could eat more, drink more and lift heavier dumb bells than most men, yet this man died of a comparatively slight ailment. Heart failure in this case meant simply a myocarditis from gout and over strain. Some of my readers may recall the "white spot" in the soldier's heart which was recognized as a result of over exertion years before we knew aught of myocarditis.

The probable disastrous effects of a continuance of his work involves degeneracy of the blood vessels. It has been said that "a man is just as old as his arteries." Many a strong man has verified the truth of this to his cost. At 45, Sandow will be in the prime of his strength; his arteries and heart, however, will not be in the prime of their elasticity. Readjustment after strain will be no longer possible. Degeneracy of arterial walls and cardiac fiber will occur; dilatation of the heart and trouble with the coronary and minute cerebral arteries is likely to develop. Apoplexy and aneurism are possibilities. The lungs will lose their elasticity and emphysema will supervene. Verily the athlete's lot will then be by no means a happy one.

Sandow is a wonderful man, but his example is pernicious. His system of muscle building is superb; its application may be dangerous.

In looking at Sandow's enormous muscles I was reminded of a remark made by my old teacher many years ago. Pointing to a cast of an enormously muscular arm upon the wall he said: "Boys, remember that such a biceps is possible, but only at the expense of life; the man from whom that cast was taken died in its acquirement." Truly, a man is not a horse and may not do the work of a horse and live. Athletics for health, should be the motto of the man who trains. Athletics for big muscles and competitive feats of strength and endurance are pernicious, illogical and dangerous. Let the man of spare muscle remember the personal equation and not try to make a Samson of himself. One may not gather figs of thistles. The average man had better content himself with perfect control and excellent nutrition of muscles of even mediocre development than to emulate Sandow. From personal experience I am also inclined to advise against getting into so-called perfect training. Especially would I advise against attempts to become expert general athletes on the part of men who lead sedentary lives or who are brain workers.

The best exercises are those involving more or less skill and active attention; the more like play the better.

A man may use dumb bells and think of the price of wheat; if, however, he is engaged in boxing, wrestling, fencing, base ball, hand ball or tennis, he is apt to pay strict attention to the subject in hand.

Cheerful companionship is essential. When patients ask me what they had best do in the gymnasium, I usually advise them to play boy for an hour and follow the play hour by a bath and a good rub down.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, IN CLIPPING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the
Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 16, 1893.

THE FUTURE GREAT UNIVERSITY.

The meeting of the Pan-American Medical Congress was attended by few, if any, of the unfortunate misunderstandings that so frequently leave unpleasant memories.

No congress, medical or secular, has ever had deeper motives of patriotism for its mainspring. The medical profession of the Western hemisphere were anxious to take the initiative steps in the formation of this new medical union, which means the emancipation of the profession of medicine of this part of the globe from European control.

This great change can not be immediate, but it is sure. The future medical students of Pan-America will attend the universities of the United States, Mexico and South America. Berlin and Paris schools will attract them no more than the older institutions of Padua and Leyden.

The progress of civilization is ever westward. Athens and Alexandria were succeeded by Salernum and Cordova; they in turn by Paris and Edinburgh.

Boston and Baltimore now claim a share in the leadership, closely followed by Philadelphia, New York, Chicago and others.

The medical schools of the cities of the United States have done very much in this Columbian year to place them in the front rank, but the history of the evolution of human intelligence shows that these efforts are only bringing into view the eternal principle mentioned by BISHOP BERKELEY:

"Westward the course of Empire takes its way."

It is in no spirit of self-glorification that we write this article; but no man can conscientiously compare the technique of the methods of the MASSACHUSETTS GENERAL HOSPITAL, the PENNSYLVANIA HOSPITAL or the JOHNS HOPKINS HOSPITAL, without knowing them to be superior to those of the HOTEL DIEU, the MOABIT or the ALLEGEMEINE KRANKENHAUS. As for the London hospitals, there are none to be mentioned in

the same class, except possibly St. THOMAS, and that is so cramped in its operation and hampered by traditional customs as to resemble more the institutions of the dawn of the century than those of its close.

In the new world, then, we may expect the great university of the next quadri-centennial; and the present status of American medical education as shown in the late Pan-American Medical Congress in its Section on Pedagogy, is such as to warrant the hope that not only will the United States in its turn, for its due season, be the seat of the world's great medical school, but that the time is near at hand.

One may not sufficiently lift the veil obscuring the future to show what American city may have this great honor, but it certainly will not be established in any city where the profession are self-sufficient, where they are already finished to an extent that prevents them from taking part in the professional exercises of Pan-American conventions, or the entertainment of their invited guests. When the profession of a city become so wrapped up in their own affairs as to become oblivious to what is going on about them, the outside world will certainly allow them that peace and quiet which betoken decay and dissolution.

THE ARMY MEDICAL EXHIBIT AT THE WORLD'S FAIR.

The exhibits of the Medical Department of the United States Army are in charge of Captain LOUIS A. LA GARDE, Assistant Surgeon, U. S. Army. They are contained in a regulation post hospital, of eighteen beds, and in a field hospital adjoining.

The Regulation Hospital.—This structure is built of frame and staff. It is divided into a ward and the administration part. The latter has two stories, having four rooms upstairs and five downstairs. In the original plan, the latter furnish rooms for kitchen, dining-room, store-room, dispensary and post surgeon's office. The ward is a large room, 56x24, leading from the main hall of the administration building.

As the exhibition of one or two beds would illustrate the pattern of bed and bedding used in army hospitals, it was not considered advisable to have more than a sample or two of beds in the ward, and the rest of the valuable space in this part of the building is devoted to the display of specimens from the Army Medical Museum and some of the supplies furnished the medical department at every army post. 1. we find the surgical instruments among which we have noticed some aseptic cases from the finest makers; 2. the pouches and first aid dressings carried by the Hospital Corps men in times of war; 3. the chemical and bacteriological sets for the analysis of air and water and soil; an elaborate out-

lay for the use of those officers practiced in matters of theoretical and practical hygiene. 4, a collection of wet and dry preparations illustrating different pathological lesions; 5, models to show the evolution in hospital construction, and transportation of the wounded in war; 6, 300 bromid enlargements and transparencies, illustrating pathological and histological lesions of various kinds; 7, a series of eighty consecutive sections of bone illustrating the form and structure of the osseous tissues; 8, ten series of consecutive sections of human embryos illustrating the anatomy of the various portions of the body; 9, a collection of microscopes showing the evolution of the instrument; 10, a collection of deformed bullets, and lesions of bone, recent and remote, from gunshot injuries, gathered from cases during the war of the rebellion.

These specimens form a great contrast with a collection of sixty specimens of bone in the opposite corner of the room which illustrate the effects on bone of the German silver mantled projectile of 30 caliber. Each specimen here is mounted, with the bullet which inflicted the injury beside it, and the slight deformation of the projectiles and their tendency to perforate the spongy ends of bone—circumstances which add so much to the so-called humane phase of the rifles of small caliber now forming the armament of all foreign nations,—are among the more striking pictures of this important collection. The specimens show the difference in destructive effects between the old leaden bullet of 45 caliber, which our army has used since 1874, and the 30 caliber projectile which we are about to adopt with the Krag-Jorgensen gun. The specimens were prepared by Dr. LA GARDE, U. S. Army, at Frankfort arsenal last winter for the exposition. The cadavers were consumed in testing the effects of the projectiles at all the distances between the 100 and 2,000 yard ranges. Those who would wish to see the ravages of the past and future wars on bone should not fail to examine this collection.

The rooms downstairs contain supplies and the records kept by the medical department. Two of the rooms upstairs are thrown into one large room, by sliding doors, which is used as a clinical laboratory for the inspection of practitioners of medicine only. The object of this laboratory is to show a clinical laboratory to a general hospital in time of war. In appointment it was largely patterned after the clinical laboratory of the Johns Hopkins hospital. There are eleven microscopes displayed, by the aid of which pathological, histological and bacteriological specimens are shown. There are a number of thermostats in operation, and the collection of cultures on various media is all that could be desired for the study of bacteriology from the general practitioner's standpoint. Dr. E. H. WILSON of the Mary-

land laboratory is the bacteriologist, and there are two medical officers and subordinates constantly at work.

The Field Hospital.—This part of the display is under canvas. It is probably the most elaborate attempt ever made by an army medical department to show the resources of surgery and first aid on the field of battle. It consists: 1, of a wall tent for the medical officer which contains a field desk, folding cot, tables and chairs; 2, a hospital tent in which sick call is held, and where the records and dispensary supplies are kept; 3, two hospital tents pitched end to end to be used as a ward. These contain twelve cots neatly made up with the field linen, bed-sacks of straw, blankets, etc. The field furniture for the ward is limited to folding chairs and tables; 4, a hospital tent, called the squad tent for the detachment of the hospital corps on duty, eight in all. These men are drilled twice per week in the methods of rendering first aid and transferring wounded and sick soldiers from litters to ambulances, etc.; 5, shows a wall tent to be used for cooking, the Buzicot oven and other cooking utensils; 6, a hospital tent to be used as a dining-room in which is shown the folding chairs and folding field dining tables, a food and mess chest; and 7, a common wall tent containing a bed pan and earth closet. The present field furniture of the medical department has been only recently adopted and it shows the display of much ingenuity and forethought for the care of the sick.

BIOLOGICAL PROBLEMS OF DEATH.

In some of the recent German reviews this topic has been discussed at some length. Death is called a definite arrest and change of life. This can only occur among multicellular beings, and is not found among unicellular organisms. These latter increase by fusion, growing to a certain stage, then dividing into two parts alike in size and structure. These organisms may be called immortal, because if protected from violent death live on indefinitely. The individuals of these unicellular species on the earth to-day are far older than mankind, and as old as life itself.

In the multicellular organisms, reproduction comes from certain germ cells in which the whole body participate. In the higher organisms of this class two forms of cells exists. One the somatic, the other the reproductive; the former suffer death and change, the latter continue. Death is simply adaptation to new conditions. Death does not necessarily follow reproduction, although the purposes of the organism are fulfilled in part by this act.

Life goes on continuously; the forms change by death and adaptation to circumstances, but one unbroken line of march exists from the first.

Reproduction is the point of change, when the

forces of the old organism pass into a new state for the continuance of life under more favorable conditions. In a large class of organisms death follows this act. Death in old age is simply the limitation and end of the power of cell production. Life in the body is a continuous death and reproduction of cells. After a time the equilibrium is broken up, a certain class of cells become exhausted and die, and are not replaced or eliminated, and interfere with the functions and economy of the body. The division of labor in the cell organism is broken up, and some particular cell function is arrested. The dead and worn out cells are not replaced, and become an obstacle for the destruction and obstruction of other cells. The work which these cells fail to do must be done by others, whose normal activity will be taxed to its utmost, followed by early exhaustion and death. Both the cells and the reproductive cell function reach the limit of their existence; this is death. This cell life and renewal is finite, and death is simply the limit of existence. This may occur from shock in which this point is precipitated, and a sudden arrest of all these cell processes follows.

The utility of this process of change called death is a part of natural selection which further increases the preservation and distribution of new structures. It also enables the germ cell to enter into new forms of life, and escape from limitations which have bound it down. Artificial death may appear at any stage of the organism, and the vital forces be overwhelmed and unable to continue cell life, and both somatic and germ cells perish.

The duration of cell life is governed by fixed conditions within itself, and the surroundings and their influence over it. The germ life goes beyond this, and is only limited by conditions essential for its perpetual existence. Death is inherent for cell life; an eternal prolongation of these cells would impede and be injurious to the organism. In the higher animals this prolongation of cell life takes place long after reproduction has occurred, obviously to assist and protect the new organism. Also the period of reproduction is greatly extended in the higher species, to provide against all possible danger of extinction.

The theory of the possible continuance of cell life in the organism, by some form of drugs that would suspend activity, is an impossibility. Each cell has a separate existence of its own, which comes to an end and is replaced by others, uninfluenced by conditions only to a limited extent. The natural duration of life is only the measure of this existence in the cell colonies of the organism.

The germ cells continue a cycle that approaches nearer to immortality than anything we know of in nature. The molecular structure of somatic cells becomes worn out and dies, but the same structure

of germ cells goes on repeating itself, beginning again anew as long as favorable conditions continue.

Like the circulation of water on the earth, it is evaporated, condensed into clouds, falls to the earth as rain, and continues the never-ending cycle. Interruptions may occur at different points, and its circulation vary. So the ceaseless round of protoplasm may halt and change for a moment, only to go on again in the same course. The mortal cells have their cycles and are replaced by others, and this continues until the larger cycle of cell colonies is completed and what we call death follows, and the form or organism disappears.

This is the grand process of evolution in which life and death are inseparable, essential, and parts of the race progress.

MENTAL CAPACITY SUFFICIENT TO SUSTAIN MARRIAGE IN LAW.

Every valid contract requires the concurrence of two or more persons, each of sufficient mental capacity to give an intelligent consent thereto. This requisite applies as well to matrimonial, as to commercial and property contracts. The old doctrine that the mind, though it has different faculties, is one and indivisible, and that, if any of its parts are disordered, or if it is in any way diseased, or its healthy operation in any function disturbed, it is an unsoundness of mind which affects the whole organ, and renders the person legally of unsound mind, and incapable of entering into a civil contract, is no longer recognized. The question under the present state of the law is not whether the mind of the party was in any way affected or impaired, but whether, such being the case, the impairment or defect of the mind operated upon or inspired the act which is the subject-matter of consideration: for, admitting that the party was subject to some delusion, or that his mind was in some faculty impaired, if the act challenged is not traceable to, and has not probably been influenced by the defect of intellect, but is the result of the action of the unimpaired faculties of his mind, it will not be disturbed. These statements are made by the court of chancery of New Jersey in the recently decided case of *KERN v. KERN* (26 Atlantic Reporter 837) brought for the annulment of a marriage as void for want of mental capacity in one of the contracting parties. The court in a very lengthy and carefully prepared opinion, wherein it reviewed many authorities on the subject, further says, among other things, that the test in the case of ordinary contracts is, did the person whose act is brought in judgment possess sufficient ability at the time he did the act to understand, in a reasonable manner, the nature and effect of his act, or the business he was transacting? If he did, his act is valid. He may have been old or enfeebled by disease, or

irrational upon some subject, yet, if he had sufficient ability to comprehend in a reasonable manner what he was doing, his act will bind him. This is the rule in the absence of fraud. And the weight of the authorities is that no greater, if as much, mental capacity is requisite to make binding matrimonial, than is required to make ordinary business contracts, or a valid testamentary disposition of one's estate. There seems to be less difficulty in bringing to a test the acts of a person whose mind in its normal condition had been sound, but which has subsequently become affected, and subject to some delusion, than to establish any test with reference to the acts of one whose mind is weak or undeveloped; for in the first class the characteristics of the mania or delusion will probably make themselves apparent in the act, while as to the other, the border line between mental capacity and imbecility is so dim and indefinite that it is often difficult to determine whether the act has been guided by the light of reason, or done within the shadow of a darkened intellect. The abstract opinions of medical experts as to a person's mental condition may be entirely satisfactory in the consideration of the subject from a medical standpoint, but, in the solution of questions involved in judicial investigation, they must be tested and qualified with reference to the facts on which such opinions are based. A man may be mentally unsound in a medical point of view, from certain conditions which exist, which would not in a legal sense relieve him from responsibility. He may be subject to mania, and medically of unsound mind; yet, if the peculiar phase of mania had no influence upon the act brought in question, such act is not in the law invalidated. He may be an imbecile, and medically of unsound mind, but, if he has sufficient mind to reasonably understand the act, which is brought in question, he is legally competent. Each case must be decided on its own circumstances, and the ability of the party to understand can in no more satisfactory way be ascertained than by referring to his conduct in other transactions. Without attempting to formulate a rule to be adopted as the test of mental development of a person afflicted with congenital imbecility necessary to exist so as to bind him in making a contract, recognizing that each case must be governed by its own incidents, it would seem that if a person, in a general way, had an appreciation of the conditions of the marriage state, and understood the rights and responsibilities which attach thereto, and regarded the marriage ceremony as the incident which effected a marriage between himself and a certain woman, he should be held bound by a contract which he entered into under those conditions. There was in this case, as shown by the evidence, a person of weak intellect; one who at times might not express himself coherently, but

who, until he was 35 years of age, had been permitted by his family to take care of himself and his property; one who had contracted no bad habits, and who had so taken care of his estate that it had been preserved, if not increased; whose memory was good; who, in making a bargain, manifested shrewdness and judgment; and who, in reference to the marriage in question, conducted himself without impropriety or peculiarity; a person who seemed to have had a proper conception of the ceremony which was being performed, and to understand the rights, duties and responsibilities which attach to the marital relation. While the conditions were no doubt sufficient to clear him as of unsound mind from a medical standpoint, the court did not think he could be said to be legally irresponsible, and decided that it would not be justified in annulling a marriage entered into under such circumstances, because of the alleged weakness of intellect of a contracting party.

PAN-AMERICAN EXCURSION.

[From the Philadelphia Press.]

Philadelphia, always hospitable to visitors, gave a particularly gracious reception September 9th, to the distinguished delegates to the recently adjourned Pan-American Medical Congress. In the party were nearly 100 medical men, and a few of them were accompanied by their wives. The event of yesterday which will be longest remembered by the delegates was the reception held in their honor at the University of Pennsylvania by Provost Pepper, the trustees and faculties of that institution of learning.

The grounds and buildings of the University were thrown open to the visitors for inspection when they arrived at 3:30 o'clock, and under the guidance of Dr. Pepper they visited every department, lingering longest in the medical and surgical departments whose splendid equipment they much admired. After the inspection of the buildings the members of the party were grouped about the entrance to the library building and photographed. They were then invited inside and a collation was served. When coffee was brought in and cigars were lighted, Dr. Pepper rapped on the table with the handle of his knife and the talking ceased. He stood up, and called for Dr. Chas. A. L. Reed of Cincinnati, to come forward.

A PLEASANT SURPRISE FOR DR. REED.

Nearly every one except Dr. Reed knew what was about to take place, but he up to that time had been enjoying himself unobtrusively. He approached Dr. Pepper in some embarrassment, not divining exactly what it all meant. Dr. Pepper laid his hand affectionately on the shoulder of Dr. Reed and in well chosen words praised the work of that gentleman in bringing about the convention. He gave Dr. Reed a larger share of credit for the success of the convention than any one else, and then he said: "Your fellow-delegates of this convention decided that the occasion should not pass without some expression of our gratitude to the man who has done so much of the work which made it successful, and in order that in future years he and his descendants may remember this Congress we have prepared this piece of plate (uncovering a silver salver) on which we have had inscribed these words: 'Presented to Dr. C. A. L. Reed of Cincinnati, O., secretary general, by members of the First Pan-American Medical Congress, Washington, D. C., September 4-8, 1893, to commemorate the brilliant suc-

cess—largely due to his faithful and devoted efforts in its organization—of that important occasion, when, for the first time, the representatives of the medical profession of the Western Hemisphere met in council for the advancement of science and the promotion of the public health.”

Dr. Pepper handed the salver to the surprised secretary general amid the hearty cheers of all the delegates. Dr. Reed said, in accepting it, that a salver was used for handing food and drink to those who are hungry and athirst, and he would always look upon this particular salver as being laden with the friendship of his colleagues.

Dr. A. M. Owen of Evansville, Ind., then covered Dr. Pepper with confusion by making a retaliatory speech, in which he said a number of pleasant things about the doctor, and finished by presenting him with an ivory gavel suitably inscribed. Then the speech making became general in a diversity of languages. After the reception the delegates returned to their hotel thoroughly tired, for they were sight-seeing from early morning.

They arrived at the Broad street station from Baltimore at 4:30 a. m., and remained in their sleeping car until 7 o'clock, when the Committee of Arrangements from the University, whose guests they are during their stay in Philadelphia, called for them at their coach. The committee consisted of Dr. John Marshall, chairman; Drs. James W. Holland, Ernest Laplace, Charles W. Dulles, Hobart A. Hare, E. E. Montgomery, Edward Martin, James W. Ruders and De Forrest Willard.

The party was conducted to the hotel, passing through the court of the city buildings, where a stop was made to inspect the bronze statue of William Penn. It is told of one of the Washington doctors that he pointed out the statue to the foreign gentlemen as being that of the great Dr. Benjamin Franklin. The Washington guide afterward gave as his excuse that he could not see distinctly at such an early hour of the morning.

RECEIVED BY THE MAYOR.

After breakfast at their hotel the visitors were conducted to the city hall, where Mayor Stuart welcomed them. In his speech the Mayor said:

“Gentlemen:—Philadelphia feels herself honored by the presence of such a distinguished body as the Pan-American Medical Congress, yet it seems particularly appropriate that you should so visit us, for the early—in fact, almost the entire—history of our city is closely allied to the history of medicine in this country. While we regret that your stay with us is somewhat limited, we hope that while you are here you will not only see all that pertains to the study and history of medicine, but that you will also see some of the material prosperity and industries of this great American city, and it affords me much pleasure in the name of the people of Philadelphia and on the behalf of the medical profession to extend to you a most sincere and heartfelt welcome to the City of Brotherly Love, hoping that your visit may be agreeable to you, as the remembrance of the same will always be to me.”

After going over the public buildings the visitors repaired to the mint, where they saw the several processes of coining money; then they went through the Jefferson Medical College, and Independence Hall, from the latter place going to the Walnut street wharf, where several tugs took the party to Cramps'. They were cordially received by Henry W. Cramp, who conducted them over the battle ship *Indiana*, which is the nearest finished, and then through boiler and machine shops. At noon lunch was served in the company's offices. Then they went aboard the tugs and took a trip to League Island, where they had a look at the new United States cruiser, *New York*.

From League Island the party returned to the city, and made a hasty tour of other places of interest, taking in the Medico-Chirurgical College and the Drexel Institute, and then to the University of Pennsylvania.

WILL INSPECT REEDY ISLAND.

Saturday the delegates will leave from Broad street at 9 o'clock a. m., for Newcastle, Del., where they will go aboard the revenue cutter *Hoodton*, and go down the bay to Reedy Island, where they will be received by Surgeon General Wyman, who will show them around the United States quarantine station. They will return to Philadelphia at 4:30 o'clock and will leave at midnight for New York.

The personnel of the party is as follows: Samuel S. Adams, chairman; M. C. Y. Valle and son, Rafael Lavista, E. R. Garcia, Jose Myta, Juan Zavata, Domingo Owananos, J. E. Monjaras, Francisco Marin, J. Martinez del Campo, Louis G. Munoz, A. Contreras, L. E. Ruiz, E. Liecage, R. Yeaza, Thomas Noriega, Angel Gaimo, Fernando Zarzaga, Manuel Gutierrez, Roge Macuzet and A. W. Fernandez of Mexico; Thomas Casas y Marti, Jose Clairie, Enrique Lopez and Antonio Touer of Cuba; F. A. Risquez, Rivero Saldivia and David Lobo of Venezuela; Alfredo Gares, Guillermo V. Poredes and Daniel Gutierrez of Colombia; Pedro Lagleyze and Juan Mendieta of the Argentine Republic; J. C. Philippo and R. S. Surton of Jamaica; Augusto Cemeu and V. L. Gilles of Haiti; Jitan Padilla of Guatemala; Juan L. Ulloa of Costa Rica; Juan Hernandez of Porto Rico; Bayen Rake of Trinidad; Florestan Aquilar of Spain; Dr. Wolve of Scotland; Drs. Holton of Vermont; Cushing of Boston; Rohé and McShain of Baltimore; I. N. Love of St. Louis; J. V. R. Hoff, F. S. A.; J. M. Anders, Ernest Laplace, E. E. Montgomery and S. A. Martin of Philadelphia; Drs. Cook, Kleinschmidt, Eliot, Johnson, Barker, Bowen, Waggoner, Acker, Morgan, Ober, Gutieras, Walton, Wellington, Happer, Jules Guthridge, J. Pores and R. M. Larnier of Washington, D. C.

The party is made up of many who are not only representatives of the profession, but are distinguished citizens of their respective countries. Dr. Rafael Lavista of the City of Mexico is the personal physician of President Diaz, sustaining practically the same relation to him that Dr. Bryant sustains to President Cleveland. Dr. Carmona Y. Valle is the distinguished dean of the faculty of the National University, and is perhaps the most renowned medical practitioner of the republic. Dr. Eduardo Liecage is the president of the National Council of Health of Mexico, and is possessed of extraordinary power in the enforcement of quarantine and other sanitary regulations. Dr. Juan J. Ulloa is the official representative of the government of Costa Rica. He is a graduate in medicine from New York, is highly influential in the government councils of his own country and is thoroughly American in all of his sympathies. Dr. Duenas is a prominent professor in one of the leading medical schools of the United States of Colombia. Dr. John C. Philippo is the president of the Legislative Council of Jamaica, and is concededly the most distinguished citizen of that colony. Dr. Munoz of Peru, is a prominent officer in the army medical service and stands high in governmental circles. Dr. Francisco A. Risquez of Caracas, is the practical censor of the medical profession of Venezuela, and is especially delegated by his government to participate in the hygienic deliberations of the Congress. Dr. Pedro Lagleyze, the delegate from the Argentine Republic, is a prominent editor and an eminent ophthalmologist of Buenos Ayres. Dr. Clairac is the surgeon General of the Spanish army in the West Indies.

“The significance of these facts,” said a member of the Congress, “is that in entertaining this distinguished delegation the citizens of Philadelphia are securing the friendship of people who are capable of largely controlling the course of affairs in their respective countries. Further reciprocity will be much more easily effected in the future than before the friendship of these gentlemen had been secured through the side avenues of fraternal feeling and professional interest.”

DOMESTIC CORRESPONDENCE.

Dr. Hammond Replies to His Critics.

Dear Sir:—In the last number of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION there is a communication from Dr. D. R. Brower transmitting the details of an analysis made of cerebrine and medulline, said to have been prepared by my formulas. Of course I have no assurance that the specimens examined were really what they purported to be, neither does Professor Delafontaine, who made the analysis so assert. He examined what was given him and I have no disposition to question his honesty in the matter.

I have only to say:

1. That the cerebrine as prepared by my process is a solution obtained by macerating the brain of the ox and the contained blood for from six months to a year in a mixture of equal parts of absolute alcohol, glycerin, and a saturated solution of boric acid in water, with frequent agitation and the application of strong pressure. As Professor Delafontaine does not mention either the alcohol or the solution of boric acid, but declares that the excipient of the sample he examined "was chiefly glycerin," it is quite certain that the specimen given him was not prepared by me.

2. But admitting that the sample was genuine, his discovery of a substance, either "nitroglycerin or some very closely allied product which does not preëxist in the ox brain," was partially anticipated by me several months ago, as you will perceive by the following quotation from my original paper on "Certain Organic Extracts," published in the *New York Medical Journal*, January 28, 1893:

"It may be that the mixture of boric acid, alcohol and glycerin exerts a metamorphic influence and causes the formation of a ferment having the power of restoring to the weakened brain or other viscous the lost or impaired power of assimilation."

3. It was fully anticipated in a paper entitled "A further Contribution to the Subject of Animal Extracts," published in the *New York Medical Journal*, July 1, 1893, as the following quotation shows:

"The immediate effects of the cerebrine and of most of the other extracts are those indicating vaso-motor disturbance, and are so far similar to those produced by the nitrite of amyl and trinitrin or nitroglycerin. It is of much longer duration but not so intense as that produced in the average person by a drop of a 1 per cent. solution of nitroglycerin. I have experimented largely upon myself and others with fresh extracts of the brain mixed with solutions of nitroglycerin of various strengths, and I am convinced of the great difference in the action of these mixtures and of cerebrine prepared according to my formula. It has been observed by those who have employed the extract of the thyroid gland in the treatment of myxedema that even more severe symptoms usually follow the administration. These are in the form of giddiness, headache, faintness and an apparent tendency to convulsions, and occasionally it has been found necessary to suspend the treatment on this account. Similar effects to those produced by cerebrine are generally observed from the hypodermic injection of the extract of nerve substance prepared by Dr. Gibier. I have never in a single instance—and I have used them many hundreds of times—observed the slightest alarming effect from the use of the animal extracts prepared according to my method.

"I have sometimes thought that the combination of glycerin, alcohol and the highly nitrogenous substances from which these extracts are made might result in the production of a subject analogous to nitroglycerin, and in my first communication on the subject to the *New York Medical Journal* I threw out the suggestion of a secondary product being formed. As I have said, however, the thorough chemical analysis which is now being made will, I hope, dissipate the uncertainty which necessarily exists relative to the exact composition of these extracts."

This, to some extent at least, takes away from Dr. Brower and Mr. Baker the honor of having made an original discovery relative to the physiological effects of cerebrine.

4. The fact that Professor Delafontaine detected no organic matter is sufficient to enable me to assert positively that the specimen submitted to him was not prepared according to my formula. Every analytical chemist will admit that it would be impossible for finely comminuted brain substance and blood to remain several months in contact with the menstruum I have mentioned without parting with some portion of their organic constituents.

5. Either Professor Delafontaine's analysis was very superficial and inexact, or the mixture he examined was glycerin to which nitroglycerin had been added. It certainly was not cerebrine.

6. It is impossible for Professor Delafontaine, or any other chemist, to say what would be the results of the long continued maceration of brain substance and blood in alcohol, glycerin and solution of boric acid. He may express his non-belief "in some putrefactive process, generating a nitrate, in the Hammond product," and I fully agree with him in this, for there is no putrefactive process, and consequently no ptomaines. But should he declare that no leucomaines could be generated in such a mixture, he would be exhibiting a degree of temerity which I venture to hope he is not capable of showing. He can not be unaware of Schreiner's discovery of spermine, and he doubtless himself has seen crystals of this substance, as I have for many years, on nervous tissues preserved for several months in alcohol.

7. And I thoroughly agree with him when he says: "On the other hand, a sample of cerebrine made by another firm proved to be physiologically inert, and utterly failed to give any of the color reactions described in the foregoing lines."

8. My laboratory is at all times open to the inspection of chemists and physicians, and specimens of the extracts, taken directly from the vessels in which maceration is going on, are at their disposal for such examination as they may see fit to give. Yours respectfully,

WILLIAM A. HAMMOND.

Washington, D. C., Sept. 2, 1893.

Hughes—Moyer—Hinde—A Correction.

To the Editor.—*Sir:*—In the current number of the JOURNAL appears the "Address of the President of the Section on Neurology and Psychiatry of the Pan-American Medical Congress," which I have just read with interest and profit. As a matter of fact, however, I wish to correct that which concerns myself. In referring to the work of my friend, "Moyer, the tireless," Dr. C. D. Hughes (p. 387) gives him the exclusive credit of reporting the first case of "Periodically Recurring Oculo motor Paralysis" in this country, and in parenthesis refers to the *Medical Record*, 1887. The facts of this case are as follows: The case was referred to me by my friend Dr. D. O'Shea, and recognizing it as of rare and special interest, I showed it, in my regular work, at Prof. Holmes' clinic at Rush Medical College, and later at the neurological clinic of Prof. Lyman, who also recognized the rarity of the case. It was first seen by Dr. Moyer at the latter clinic, and he asked to share with me in the report of the case, to which I unselfishly agreed. It still continued to be my case, however, as will later be evident. Together we prepared the first paper. When it was ready Dr. Moyer asked permission to read it before the Chicago Medical Society, of which I was not then a member. I agreed to this, expecting, of course, an equal division of praise or blame would be shared by both of us. Dr. Moyer, however, inadvertently left me out of the paper and the case altogether, though I was

present at the meeting as an auditor—a surprised auditor I admit.

The paper was then turned over to me and I sent it to the publication for the *Medical Record*, and it appeared in the issue of September 21, 1887, as a joint report of Dr. Moyer and myself. The case continued solely under my observation, however, and without the knowledge of Dr. Moyer. I wrote a second paper on the case that was forwarded to the *Medical Record* and published in the issue of October 22, 1887, a full account of which may there be found (pp. 526-528). Silence may be a great virtue, and hence has been longed for, but I feel that credit ought to be divided in this instance, and I request you to kindly publish this communication.

ALFRED HINDER.

ASSOCIATION NEWS.

Loyal to the American Medical Association.—An editorial in a current issue of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION takes occasion to point out that the statements published in the JOURNAL immediately after the annual meeting this year have a tendency to belittle the affairs of the JOURNAL and also of the Association.

The editor says that the reason of this is not on account of what was published, in which case there would be no need of an explanation, but that certain more or less unfriendly journals to the Association have published and given wide circulation only to parts of the editorial mentioned, and not the whole article.

Dr. Hamilton, the present editor says, that at the last meeting there was an increase in membership of 273, and in the last month, the membership by application has brought the increase up to 300.

Also, there has never been a time when the JOURNAL had so large a bona-fide mail list, and there has never been a moment when there was not money in the treasury; more than sufficient to meet any possible contingency. There have been added eight pages of reading matter, and the outlook for the publication has never been brighter than at present.

The *Omaha Clinic* should dislike exceedingly to be classed as one of the "not over-friendly publications."

This not over-friendly spirit and the spirit of indifference is not manifest in the West; if there is such it must emanate from somewhere "down East." There may be sporadic cases in the West, but their ideas have been brought with them from the other quarter.

We regard the American Medical Association as America's only truly national medical organization, and in proof thereof we adduce that it is only here that we can expect to find those questions of vital interest to the profession fearlessly discussed by representatives of all parts of this country. The fact that the American Medical Association stands in this broad manner to the profession, necessarily lays it open to the sharp attacks of individuals and more close organizations.

The *Omaha Clinic* regards it as its imperative duty to instruct societies all along the line in its influence, to lend their aid to the Association to build up the profession.

When we differ with the Association it is by virtue of an honest interest in it for that which we think is best for the profession and to be so held by its representative organization.

Never has this journal differed with intent to disparage, or to lend aid, or to further the interests of any organization to take its place.

The constitution of the AMERICAN MEDICAL ASSOCIATION is open to a change when the profession demand it by a legitimate vote, and there is no constitutional democratic government on earth in any way different from this. We truly hope that next year the ASSOCIATION will take up the issues which seem so urgently pressing—the remedy, when necessary, is in the hands of the members—and show this country, East, North, South and West by a majority vote as to what is the present will of the profession to be stamped in the year 1894 on our medical government.

To do this, according to the advice of ex-President Hunter McGuire we should like to take this occasion to point out that, if as so recommended, a fair opinion be had from all sections of our country, well represented, in changing the

constitution, and also that which Dr. Roberts of Philadelphia, declared is a part of it, namely the code, then by all means something must be done toward placing the date of meeting for San Francisco in June, and not the first week in May as the constitution of most State societies require that they meet not earlier than May and the State societies will be able each to voice its opinion on the issues, which when engrafted upon the AMERICAN MEDICAL ASSOCIATION, will certainly show to the indifferent East and the interested North, South and West, whether the ASSOCIATION is America's representative body and represents the views of the American profession.—*Omaha Clinic*.

SOCIETY NEWS.

The American Medical Editors.—The American Medical Editors' Association met in Washington, in the large banquet hall of the Arlington hotel on Monday, September 4. The President, Dr. C. H. HIGGINS, of the *West and North-west*, read a short and pithy address of welcome to the invited guests, and the versatile vice-president of the American Medical Association, Dr. I. N. LOVE of the *Medical Mirror*, was toast master of the evening. To the toast of the "President of the United States," the Hon. J. Sterling Morton, Secretary of Agriculture, responded in a most happy manner. "The Secular Press," was responded to by Hon. Frank Hutton, editor of the *Washington Post*; "THE AMERICAN MEDICAL ASSOCIATION," by President J. F. Hibberd; "The Pan-American Medical Congress," by President Pepper; "The Medical Press," by Dr. Hobart A. Hare of Philadelphia; "The Surgeon General of the Army," by Ex-Surgeon General Hammond, General Sternberg being absent; "The Surgeon General of the Navy," by Ex-Senator John B. Henderson of Missouri, who gave an interesting account of the purposes and objects of the Pan-American Congress over which he presided last year; "The Public Health," and "THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION" by Dr. John B. Hamilton.

The volunteer speeches brought out by the skillful touch of the toast master, were many and excellent. Among the most notable of the after dinner volunteer speeches were those of Dr. Ernest Hart of the *British Medical Journal*, Dr. Phillipot of Jamaicaica, Dr. Abram Owens of Evansville, and Dr. Garcelon.

In the intervals between the speeches, Major Stoffer, the well known Washington correspondent, rendered some pleasant musical selections, and Mr. Seabrook the actor gave one of his characteristic recitations.

As the evening waned, it devolved upon some of the invited guests that American medical editors knew how to enjoy themselves, and take a few hours of recreation, as well as any other class of Pan-American citizens.

Pan-American Comments.—The Section meetings were well attended, the papers excellent, and management as good as should have been expected. There were some papers discarded, but they may easily be placed in proper position when the Transactions come to be printed. The practice of subdividing the general Sections into many independent Sections, is one the next committee on organization will do well to avoid. There were too many papers in several Sections to allow time for intelligent discussion of all of them, and at the close many excellent papers were read by title for want of time to hear them either in full or by abstract.

The American Medical Association having invited its Pan-American guests did its full duty by them. A glance at those in attendance at the Sections, showed the familiar faces of the members largely in excess of any others, and to those members the officers of this Congress confidently appealed for support; that they were not disappointed, the magnificent success of the meeting shows.

It is pleasant to note that soon after the close of the meeting the late Secretary General Reed received a graceful recognition of his untiring labors, at the hands of his associates, and that ex-President Pepper, and the other general officers of the Congress, if not furnished with a silver token, will yet have the affectionate and grateful thanks of their medical brethren, embalmed on the record pages of this now historic Congress.

Medical Congress Adjourns—End of the Pan-American Meeting.

—RESOLUTIONS ADOPTED REGARDING QUARANTINE—THE DELEGATES START ON A TOUR THROUGH THE COUNTRY.—Washington, Sept. 8.—The final meeting of the Pan-American Medical Congress was held this morning. The Rev. Dr. Byron Sunderland, of the First Presbyterian church, the oldest pastor in Washington, opened the proceedings with prayer. Addresses of thanks and congratulation on behalf of their respective countries were made by Dr. Garcias of the United States of Colombia, in Spanish, and by Dr. Ferd C. Valentine, ex-Surgeon General of the Army of Honduras, in English, and by Prof. Rafael LaVista of Mexico.

Secretary General Reed read the report of the International Executive Committee. The committee accepted the invitation of the Mexican delegates to hold their next meeting of the Congress in the City of Mexico. The date will depend upon the meeting of the International Congress in Europe. The various recommendations by the several Sections were generally adopted by the committee. The most important exception was the one advising a temporary suspension of immigration from European countries in which cholera is now prevalent. It was deemed best, the report stated, not to consider this resolution at the present time. Thanks were given to President Cleveland, the Congress of the United States, the Surgeons General of the United States Army, Navy and Marine Hospital Service, the officers of the Congress, the local Committee on Arrangements, the press and the railroads for their efforts to make the meeting of the Congress a success. The report was adopted.

Dr. Gibson presented the following resolutions, which the Section on Hygiene, on motion of Dr. Shakespeare, had adopted:

Resolved, That the thorough disinfection, without discrimination, of every piece of baggage, dunnage or article of personal effects belonging to the immigrant classes and to the crews of immigrant ships, and the exaction of scrupulous cleanliness of all vessels arriving at American ports, should be rigidly enforced at American ports, supplementing and enhancing the protective value of similar treatment at the ports of departure, especially at times when cholera exists in Europe, as a sanitary measure, second only in efficiency and importance to the temporary suspension of immigration.

Resolved, That the habitual and thorough disinfection of all personal effects liable to carry contagions of immigrants to the American hemisphere, and of dunnage of crews of vessels carrying these immigrants from any quarter of the globe, and the exaction of scrupulous cleanliness of all vessels arriving at American ports, should be enforced at all times, as the most efficient means of greatly lessening the introduction into this hemisphere of the seeds of various contagious diseases which are now and have been in the past almost constantly conveyed by the immigrant classes and distributed widely among the populations of this hemisphere.

These resolutions were referred to the International Executive Committee. Dr. Montezambert of Canada, stated that that country had already put into effect the recommendation of the resolutions regarding the disinfection of immigrants' baggage arriving at her ports.

On behalf of the visiting delegates and guests of the Congress, Dr. John C. Phillippo of Bermuda, Professor Ernest Hart of England and Dr. Rafael Lavista of Mexico, returned their thanks for the cordiality and bounteousness of their reception and entertainment while in Washington. Dr.

Phillippo paid a warm and eloquent tribute to the memory of George Washington, whom he designated as the greatest character in history, which the Congress rapturously applauded.

President Pepper then, in a few well chosen words, expressing the purpose of those connected with the Congress to stand by it, develop it and make it more useful to the members of the profession throughout the continent, declared the Congress adjourned, to meet in the City of Mexico either in 1896 or 1897.

At 1:30 o'clock this afternoon the foreign members of the Congress, with the members of their families, accompanied by the Committee on Arrangements and officers of the Congress, left Washington over the Pennsylvania road for an extended trip through the Eastern cities, and thence to the World's Fair, as the guests of the committee, under the resolution of Congress inviting the attendance of foreign delegates. The trip will include stops in Baltimore, Philadelphia, New York, Boston, Saratoga, Niagara Falls, Detroit, Cincinnati and Chicago. Upon arrival at Chicago the 19th instant the party will separate.

The Second Pan-American Medical Congress.—The affairs of the next Pan-American Medical Congress are placed in the hands of an international executive committee, one member from each country, and that committee decided that the next meeting shall be held in the City of Mexico, at a time yet undetermined. It is probable that the winter season will be selected and that the Congress will be held five years from this date, with our accomplished colleague, Prof. RAFAEL LA VISTA of the University of Mexico, as its President.

The proposed change of time to five years, it is urged, will not only give time for complete organization and results of special experimentation but will cause the holding of the next session in the year following the International Medical Congress. Others are of the opinion that the meeting should take place in 1896, but the question is one that only our Mexican confrères can decide.

The American Electro-Therapeutic Association held the opening session of its third annual meeting on the 12th at the Apollo hall, Central Music Hall block. The President, Dr. Augustin H. Goelet of New York, called the meeting to order at 9:30 A. M., and delivered the opening address, in which he spoke of the influences governing the progress of electro-therapeutics and congratulated the Association on its growth. The afternoon session opened at 2:30 P. M. Several papers were read and discussed. That which created most interest was the paper read by Prof. William J. Morton, M.D. of New York, on "The Nutritional Effects of Static Electricity Considered in Relation to High Frequency and High Currents and Permeability of Dielectrics to Such Currents." Prof. Morton stated that the currents in question are those which have recently become known through Tesla's experiments.

Other papers read were:

"Electrolysis in Tumors of the Bladder," by Dr. Robert Newman, New York; "Electro-Medical Eccentricities," from H. Newman Lawrence, M. I. E. U. of London, England; "The Action of the Continuous Current within the Living Tissues, as Distinguished from the Local Polar Action," by Prof. W. J. Herdman, M.D., Ann Arbor, Mich.; and "Metallic Electrolysis," by Margaret A. Cleaves, M.D., New York.

At the evening session, which commenced at 7:30 P. M., the following papers were read:

"Further Observations on the Treatment of Goitre," by Charles B. Dickson, M.D., Toronto; "Notes upon Some Uses of Galvanism in Surgery," by D. B. D. Weaver, M.D., of Reading, Pa.; and "Report of a Case of Ascites Cured by Galvanism," by Halford Walker, M.D., Toronto.

A reception was given at the Great Northern hotel from

9 to 11 in the evening by the Committee of Arrangements to the members of the Association and the members of their families accompanying them.

Pan-American Medical Congress.

REPORT OF THE PROCEEDINGS OF THE SECTION ON MILITARY MEDICINE AND SURGERY.

The pamphlet program of the work of this Section intimated that on the afternoon of Tuesday, September 5, an informal meeting would be held in the Army Medical Museum for the purpose of inspecting the collections contained in this Museum and the Library of the Surgeon General's office. About fifty members responded to the call and an hour and a half was spent in examining the building, its show rooms, book cases and laboratories under the guidance of the Librarian and Curator, Major John S. Billings, U. S. A. The total number of specimens now in the museum is 32,265, and this number is steadily increasing, 1,040 having been added to it during the past year. The library contains 110,650 books and 173,000 pamphlets.

At 11 A. M. of Wednesday morning, September 6, the Section was called to order by the Executive President, Surgeon General STERNBERG, U. S. A., who opened the session by expressing his gratification at seeing present so many medical officers of the regular army and National Guards, notwithstanding the fact that the Association of the Military Surgeons of the National Guard of the United States had met so recently in Chicago. He then delivered his address which we had the pleasure of submitting to our readers in our issue of September 9. After referring to the progress of antiseptic surgery and military sanitation he suggested the conditions essential to the de novo origin of hospital gangrene and erysipelas. Under certain conditions of lowered vitality, the result probably of the toxic influence of the ptomaines elaborated by putrefactive bacteria, a microörganism ordinarily of a comparatively harmless character may invade a wounded tissue and acquiring pathogenic virulence in its new environment may subsequently be capable of existing in healthy tissue, which it destroys, and of spreading the infection of disease by the permanence of its acquired properties. Antiseptic methods of treatment may be relied on in future wars to reduce the number of traumatic infections just as disinfection may be depended upon to limit the specific febrile diseases.

To judge from the hearty applause which greeted the conclusion of the address, the views of General Sternberg were received with favor by the delegates and others who were present.

SURGEON GENERAL CHARLES SUTHERLAND, U. S. A. (retired) was then introduced. He described the organization of the Hospital Corps of the Army and the methods adopted for the education of its members and the company bearers in litter bearing and giving first aid to the wounded. As an illustration of the excellent results produced by these methods he referred to the record which the Hospital Corps had made for itself during the Sioux campaign of three years ago.

SURGEON GENERAL BERGEN of the Canadian Militia stated that in some of the Canadian regiments considerable progress had been made in teaching first aid and stretcher drill.

DR. BEDFORD BROWN of Alexandria, Virginia, a representative of the medical department of the late C. S. A., referred to his knowledge of the destitute condition of the medical department on the Southern side during the civil war. Gangrenous wounds in the field did well when isolated under tent flies and treated locally with hot water dressings and strong solutions of sulphate of zinc.

DR. P. S. CONNER of Cincinnati, Ohio, then read a paper on LAPAROTOMY IN GUNSHOT WOUNDS OF THE ABDOMEN.

He cited the large death rate from penetrating wounds under expectant management. At one time such wounds were regarded as necessarily fatal. The reports from the great wars of the third quarter of our century show that from 65 to 92.5 per cent. of the cases coming under observation terminated fatally; but they formed only a minority of the whole number of such wounds, for many cases perished quickly on the field from hemorrhage. Of cases in which laparotomy was performed, Körte collected 64 with 42 deaths or 65.6 per cent.; Morton 110 with 74 deaths or 67.27 per cent.; Barrow 112 also with 74 deaths making 66 per cent.; Martin and Hare 129 with 86 deaths, 66.66 per cent.; Coley 165 with 111 deaths, 67.2 per cent.; but all these statistics are vitiated by the errors due to the suppression of unfavorable cases. In 174 cases collected by Dr. Conner and constituting all the laparotomies performed by fifty-five medical men who reported to him as having had personal experience of the operation there were 123 deaths or 70.67 per cent. Some of the published statistics indicate that the chances of a favorable termination are greater when operative procedures are not instituted; but many of the unoperated cases that are published and thus become embodied in the statistics are reported merely because their result was not that usually observed. One of the chief causes of fatality after operation is shock and this is proportioned to the duration of exposure during the operation. A certain and safe method of determining the place and number of the lesions is greatly needed. Insufflation is unreliable and sometimes injurious. Leaving out of consideration the cases in which there is profuse hemorrhage or external discharge of feces, urine or bile—cases in which operation is certainly called for,—the propriety of laparotomy must be determined according to Dr. Conner, by consideration, on the one hand, of the likelihood of the occurrence of septic infection if it is not done, and on the other of the probable amount of shock that may be expected to attend the operation, bearing in mind, meanwhile, the fact that the necessary manipulations of the laparotomy may be a determining cause of toxemia, in the breaking up of already formed protective visceral adhesions. When the wound has been made by a small ball, caliber 22 or less, especially if it is well above the level of the umbilicus, or, without regard to the size of the bullet if it is well out from the central line of the body, and it may reasonably be expected that its course has not been towards that line and if the patient's general and local conditions are good, abdominal section should not be made. When the symptoms indicate decided hemorrhage or fecal extravasation operative interference should be made at the earliest moment. When the bullet is of medium or large size and has in all probability passed through the area occupied by the small intestines or wounded the liver, spleen, kidney or bladder the operation should be performed; and even if peritonitis has developed its presence does not contra-indicate the operation though it increases the gravity of the prognosis.

DR. VANDER VEER, Albany, N. Y., spoke of the great fatality of penetrating wounds of the abdomen during the civil war and of the more humane character of the wounds by the smaller calibers of to-day. He coincided generally with the author of the paper in his conclusion as to when the operation should or should not be performed.

DR. L. A. LA GAYON, U. S. A., in speaking of abdominal wounds from small calibers, considered that wounds inflicted beyond the explosive range would seldom call for operative procedure; but that at short ranges visceral injuries would probably be as great as with the larger bullets.

DR. BERNAYS of St. Louis, Mo., referred to the empty or full condition of the stomach and intestines as bearing on the necessity for operation. In closing the discussion, Dr. Conner urged the desirability of knowing the results of all cases of laparotomy, successful or unsuccessful, and requested those who knew of any unreported cases to inform him of the details.

At 2 P. M. the Section met on the green sward in rear of the Library and Museum Building, where a field hospital had been pitched as a practical illustration of some of the points that might be broached in the discussion on first aid announced as part of the program for the afternoon. All the members of the Section were present, with many delegates from other Sections. The Secretary of War and the Major General commanding the Army were also present, as interested spectators of Major Hoff's demonstration of hospital corps drill and army methods of giving first aid on the field of battle. A clear space in front of the tents had been roped in and was under military guard to prevent the crowd of curious onlookers from interfering with the proceedings of the Section. Major Hoff's detachment consisted of only eight men and a non-commissioned officer; one litter squad of four men from his own post, Fort Columbus, N. Y., and the other borrowed for the occasion from the detachment on duty at Washington barracks, D. C. The promptness, care and intelligence shown by these men in handling the members of the guard who acted as the wounded, demonstrated fully the efficiency of the army method of educating its corps of litter bearers. Wounds were dressed, hemorrhage controlled by tourniquet, and broken limbs put up in extemporized splints in a way that called forth commendation from every one. The drill was carried out in accordance with the program published in full in our issue of September 2, and at its close the delegates inspected the field hospital, which consisted of a dispensary tent, kitchen and dining room, tents of the medical officers and men and one hospital tent as a ward of six beds. Another hospital tent was pitched by one of the litter squads to show the delegates how promptly the accommodation of the field hospital could be extended. The time occupied in pitching the tent was four and a half minutes.

The Section then adjourned to the lecture hall of the National Museum, where its sessions were held, to continue the proceedings of the afternoon by a discussion on the methods of first aid, General Sternberg in the chair. Colonel Page summed up his criticism on the hospital corps in the sentence: "Skilled labor is better than unskilled labor." Colonel Irwin spoke of the difficulty experienced in getting the company bearers out for drill and instruction, and Colonels Alden and Forwood, in referring to this, thought it would be well to have all the men of the company instructed in the elementary parts of the drill. Major Huntington described the organization of the hospital corps and considered that it now was what it was originally intended to be, the nucleus around which in time of war we can gather the hospital men of the volunteer forces. Surgeon Beyer of the Navy, expressed his admiration for the able manner in which the first aid system had been elaborated in the Army, and regretted the absence of such a system in the Navy. Captain Woodruff spoke of the difficulties attending the operations of military surgeons in the field as compared with hospital work in civil life. Prof. Conner suggested that little is required for first aid. In many cases an antiseptic pad is all that is needful for twenty-four or forty-eight hours. Major Billings stated that after having seen the drills at Aldershot and St. Thomas, he thought the exhibit of this afternoon was perfectly satisfactory as compared with them. Major Hoff closed the discussion by defending the system of company

bearers. He had found no difficulty in getting them out for instruction or in teaching them afterwards.

A paper was then read by Capt. LOUIS A. LA GARDE, U. S. A., entitled:

ARE PROJECTILES FROM PORTABLE HAND WEAPONS STERILIZED BY THE ACT OF FIRING?—CAN A SEPTIC BULLET INFECT A GUNSHOT WOUND?

Captain La Garde's experiments authorized him to conclude that the majority of cartridges in original packages are sterile, and the majority of gunshot wounds are therefore aseptic so far as the bullet is concerned; but a septic bullet can infect a gunshot wound.

At 11.15 A. M., Thursday, September 7, the Section was called to order by Surgeon General Tryon, U. S. N. The first paper of the day, read by Colonel Irwin in the absence of its author was:

THE AVOIDANCE OF INTESTINAL DISORDERS IN THE FIELD.

by Brevet Lieutenant Colonel A. A. WOODHULL, U. S. A. In this paper the principal diarrheal causes were summarized as change of diet and imperfect cooking; the drinking of unsedimented, hard or malarious waters; alternations of temperature, and exposure to the conditions under which enteric fever becomes prevalent. As preventives a competent knowledge of field cooking; the use of an abdominal protector, such as is known in India as the cummerbund or cholera belt, and the protection of the camp from excretal foulness were strongly urged. In connection with the presidential address on the causation of hospital gangrene and erysipelas the following sentence in Colonel Woodhull's paper indicates the tendency in army medical minds to regard some of the so-called specific infectious diseases as resulting from the influence of insanitary conditions on the evolution of bacterial life. "I have long believed," he says, "that in the course of many bacterial generations, which may be included in a relatively short season, an innocent bacillus by its environment may become pernicious, and I see no reason why in the interest of safety this might not be adopted as a working hypothesis."

The paper was discussed by Colonels Irwin and Alden, Dr. B. Brown and Majors Huntington and Hoff. Colonels Irwin and Alden spoke of the advantages of post messes; Dr. Brown, of the liability of the illiterate volunteer soldier to intestinal disorders as compared with his educated comrade; Major Huntington, of the untrained company cooks of our army and the desirability of having the food of the soldier well cooked in times of peace as well as in times of war, and Major Hoff in this connection suggested a service corps of cooks, organized by and under the orders of the subsistence department.

The next paper read was by Dr. BROWN giving his personal experience in the results of good and bad sanitation in the confederate army. He described the insanitary conditions of camps in the confederate service in the early period of the war, and contrasted the non-efficiency from sickness in certain of these camps with the corresponding rates among troops living under an efficient sanitary government. The systematic location of tent sites was represented as of the highest importance. Some interesting points were mentioned in connection with the prevalence of measles in the army generally, and of cerebro-spinal meningitis in camps at Raleigh, North Carolina. The latter disease was regarded as eminently infectious and required for its suppression the prompt removal of the sick to isolated wards. Diarrhea as due to faults of cooking also received its share of attention at Dr. Brown's hands; but the keynote of his paper was a call for systematic cleanliness as the most potent agent at our command in military or civil practice for the prevention and cure of disease.

Dr. BROWN took the chair during the presentation of the next paper, which was on

THE CAUSES AND ORIGIN OF CONTINUED FEVERS IN NAVAL SERVICES.

by C. A. SIEGFRIED, Surgeon U. S. A. The studies and experience of this delegate led him to believe that all continued fevers are of similar origin in the first place, differentiating finally and becoming types only when the specialized microphytic elements have gained characteristic virulent properties and the power of transmitting them. In all forms of these fevers there is a constant blood change, eventuating in severe cases in disorganization, deposition of dissolved hematin, the cell protoplasm having lost cohesibility as a rule, the proteids of the blood being under the disintegrating influence of new substances circulating in that fluid—derivations of illy formed leucamines and enzymes. We can not draw sharp lines between these fevers until the process has become far enough specialized to form types: the enteric lesion on the one hand with the association of the Eberth bacillus, and the putrid blood condition with exanthematous skin and depositary membrane lesions on the other. In Dr. Siegfried's opinion, the direction of the etiology of continued fevers is as pointed out by Murchison. Saprophytic microorganisms invade the system during periods of diminished resistance and lessened immunity, or, as suggested by Rodet and Roux, a homeless saprophyte acquires by contact with water new and infective properties. The bacillus coli commune assumes a toxic nature within the human organism, and becomes in fact Eberth's typhoid bacillus.

At the conclusion of this paper, Captain L. G. GARDE made some remarks on the difficulty of dealing with those fevers which, associated at first with distinct malarial types, become adynamic later in the season and mingled with cases having ulceration of Peyer's patches and all the characteristic symptoms of typhoid fever. Major Hoff indicated from his experience the typhoid nature of certain of the febrile cases generally spoken of as Rio Grande fever and mountain fever.

At the afternoon session General STERNBERG took the chair and announced a paper by Dr. STEPHEN SMITH entitled

SOME FACTS BEARING ON THE CONDITION AND SERVICEABILITY OF THE STUMP AFTER AMPUTATIONS IN THE LOWER EXTREMITY AT DIFFERENT POINTS AND BY VARIOUS METHODS.

The paper was read by Major HUNTINGTON in the absence of its distinguished author. Dr. Smith measured the amount of atrophy in a series of 137 amputations of the thigh and 287 of the leg, and found from a consideration of these measurements that: In the thigh the farther amputation is performed from the trunk the greater will be the atrophy of the entire stump, while on the leg the farther amputation is performed from the trunk the greater will be the atrophy of the extremity of the stump and the less the atrophy of the body of the stump. He found also that the method of amputation had its influence on the nourishment of the stump and correspondingly on the amount of atrophy. The methods which in the thigh give the least atrophy of the stump, both in its proximal and distal portions are the skin flaps and circular of the muscles, and the posterior flap. The latter method leaves quite intact the full vascular supply to the entire covering of the stump. In this respect it might well be regarded as the best method of operation in the thigh, but these advantages are so counterbalanced by tendency of the flap to retain pus, its heavy and unsuitable position for transportation, etc., that it has but few advocates. The method by skin flaps and circular of the muscles gives results nearly as favorable as the posterior flap and much more favorable than by any other method as the circular, the antero-posterior flaps, the lateral flaps, the anterior flap, or the rectangular flap. It is greatly preferable to the posterior flap method, both on account of the facility of drainage and the neat apposition and lightness of the flaps, thus adapting it to transportation. This same method gives the least atrophy in amputations of the leg as well as in those of the thigh. Ankle joint amputations bear direct pressure on the stump, and the tendons of all the muscles employed in locomotion retain their former or acquire new attachments and are immediately and constantly exercised in the movement of the limb. Amputations through the leg, at whatever point, never furnish

stumps that take direct support, it is only when an artificial limb is accurately and skillfully adjusted that the purpose of even simple progress is subserved. Hence Dr. Smith's conclusions that "the stumps left after ankle joint amputations are far more serviceable than those resulting from leg amputation for unassisted locomotion," and "an artificial limb can be far more usefully applied to an ankle joint than to a leg stump."

In a paper entitled

AMPUTATIONS PROTHETICALLY CONSIDERED.

Mr. GEORGE E. MARKS announced that modern leg makers care nothing for "the point of election," as artificial legs can be made that can be worn on stumps of any length. Any stump that is capable of bearing weight on the extremity is preferable to one that can not. Syme's operation gives an end-bearing stump of the most favorable kind; and the methods of Pirogoff, Chopart, Lisfranc, Hancock and Hays are all capable of excellent prosthetic treatment; but in every partial foot amputation care should be taken to prevent contraction of the tendo Achillis. A stump extending below the knee is preferable to one extending to the knee, provided the stump is capable of flexion and extension. If the stump is disposed to become extended and ankylosed it will be preferable to sacrifice the leg to the knee. A stump extending to the knee is preferable to a shorter one. The condyles and nodules of the femur should never be excised in knee disarticulations. If the patella can be placed in the inter-condylic space and properly secured, it is always desirable to do so.

Professor Charles Parker of Cleveland, O., discussed these papers, expressing surprise at the statements made in regard to amputations of the foot. He had been accustomed to look upon that point of selection as in many degrees the best.

Surgeon General HAMMOND, U. S. A., retired in his paper on

THE FETTERISM OF ASEPTICISM.

He claimed that the days of antiseptics are numbered; that the washing of wounds with solution of corrosive sublimate or any other supposed germ killer, the ablution of the hands of the operator and the cleansing of his nails with microbicides, the soaking of the instruments in carbolic acid and other similar procedures are all utterly useless, except in so far as they tend to insure cleanliness, and in that respect they are inferior to soap and water. He stated his belief that in ten years or less we will look back on the antiseptic methods of to-day with as much scorn as we now entertain for the absurd use of the sympathetic powder of Sir Kenelm Digby. The remainder of his paper was mainly an extract from an old book giving an account of the first published case in which the powder of sympathy was employed.

THE LAWS OF GROWTH OF BACTERIA APPLIED TO ASEPTIC SURGERY.

was the title of the next paper which was read by its author, Dr. ROBERT REYBURN of Washington, D. C. The first point that attracted our attention in this paper was the to us peculiar application of the terms aseptic and antiseptic. We had been in the habit of considering the Listerian method as an effort to produce and maintain asepsis; and that this having been found to be cumbersome and unnecessary it had been gradually supplanted by our present antiseptic dressings. Dr. Reyburn, however, reversed the application of the terms in referring to the fact that "the theory and practice of antiseptic surgery as perfected by Professor Lister are rapidly being abandoned and the more perfect science and art of aseptic surgery is being substituted." He cited experiences illustrating the inefficiency and even harmfulness of germicides, including corrosive sublimate when used on living tissues. In surgical operations the only liquid necessary is recently boiled water. Instruments should be soaked in boiling water or exposed to a dry heat in an oven. Aseptic material should be used for ligatures and sutures. Then the wound should be dusted with iodoform, boric acid or sublimate of bismuth and protected with iodoform gauze and aseptic cotton.

"Ricochet Bullets," by Capt. CHAS. E. WOODRUFF, U. S. A., was next submitted to the Section, and was followed by "The Wounds of the Maunlicher Rifle in the Recent Civil War in Chili," by A. M. FERNANDEZ DE YBARRA, M. D. of New York city. The orifices made by the bullet were small slits; hemorrhage was slight; complications few and repair rapid.

In adjourning the Section sine die, General STERNBERG congratulated the members on having had a pleasant and profitable meeting.

New Officers, American Electro-Therapeutic Association.—On Thursday the Association elected W. J. Herdman of Ann Arbor, president; Franklin H. Martin of Chicago first vice-president; R. J. Nunn of Savannah, treasurer; Margaret A. Cleaves, permanent secretary.

NECROLOGY.

Dr. John Rae, LL.D., F.R.G.S.—This well known explorer of the Arctic zone was a graduate in surgery, in 1833, at the Edinburgh Royal College of Surgeons. Not long after graduating he received a commission as surgeon in the Hudson Bay Company. His death took place July 24, at his home in Kensington, London. The following brief account of the adventurous life of Dr. Rae has been abstracted from the *Lancet* and other English sources:

"He was a native of the Orkney Isles, and early in life made several voyages in the northern seas. In 1846 he commanded a small exploring party, which made a voyage of 900 miles to Repulse Bay, and wintered on shore there. Next year, with his companions, he walked 1,300 miles along the coast, of which he made a scientific survey, practically connecting the discoveries of Ross, in Boothia Felix, with those of Parry, in 1823, at the Strait of the Fury and Hecla. Dr. Rae's next important expedition, jointly with Sir John Richardson, in 1848, was in search of Sir John Franklin, coasting eastward along the Arctic shores, Wollaston and Victoria Lands, from the Mackenzie to the Coppermine River, after which Dr. Rae, with two men hauling sledges, traveled 1,350 miles to Winnipeg, now in the Canadian Dominion. He gained the reward of \$50,000 for intelligence concerning Franklin. His third notable performance, in 1853 and 1854, was the exploration of the west coast of Boothia to Bellot Strait, completing the map between the surveys before made by Ross, Bease and Simpson. He was afterwards engaged in Greenland and in British Columbia, upon surveys for telegraph lines. In 1850 he published a 'Narrative of an Expedition to the Shores of the Arctic Sea in 1846 and 1847.' His name will rank among the Arctic explorers of the nineteenth century."

He also wrote papers on the transposition of boulders, and the saline matters of the sea, and contributions to the learned English societies.

Dr. George R. Sullivan of Flemington, New Jersey, died in the latter part of August. He was a native of Maryland, born there in 1836. When 23 years old he obtained his medical degree from the university of that State. He settled in New Jersey, and when the war broke out he became assistant surgeon of volunteers in the 15th New Jersey Regiment. He was afterwards surgeon to the 39th Regiment. He joined the American Medical Association in 1872.

MISCELLANY.

Abandonment of Fort Bidwell, Cal.—Improved railroad communications and the settlement of the country have of late years rendered unnecessary the continuance of a number of small military posts originally established for the protection of civil communities during their early struggles for existence. Apparently it is the growth of the settlement in Surprise Valley, in the northeastern corner of California that has led to the recent order directing the abandonment of Fort Bidwell; for the post and neighboring settlements are still 135 miles from the nearest railway station and are reached only by a tedious stage ride or a more tedious march. The valley, sixty miles long, is well watered and fertile, and has supplies of pine, fir and mountain mahogany in the gorges of the mountains which surround it. The post has been in existence for nearly thirty years and now, at the time of its abandonment is probably in better sanitary condition than at any previous period of its history. The quarters are comfortable frame buildings raised on masonry piers and lined with tongued and grooved lumber. Water is piped and distributed by gravity from an impounding reservoir on a mountain stream. Sewage is disposed of by irrigation on gardens which furnish an abundant supply of vegetables for the garrison. Sickness has always been at a minimum. Typhoid fever was at one time imported by recruits from Jefferson barracks, Missouri, but this was the only appearance of enteric fever at the

station. In fact, Fort Bidwell was one of the posts at which a young medical officer had every facility for forgetting, in the course of a four years' tour of duty, all the knowledge that he had gathered prior to his graduation. No doubt a number of other military posts will soon suffer the fate of Fort Bidwell, as the policy for some time back has been to concentrate troops in large garrisons from which they can be dispatched by rail when their presence is required in other parts of the country.

The Heroine of the Crimean War.—Florence Nightingale recently celebrated her seventy-third birthday. Although a confirmed invalid, she is somewhat stronger than during the past two or three years. She still maintains an active interest in hospitals and nursing.

Cholera.—ROME, Sept. 11.—There has been a severe outbreak of cholera in Livorni (Leghorn), in a dirty quarter of the town named Venezia. In this district yesterday 205 cases and several deaths were reported. The record in other infected places for twenty-four hours is: Naples, five deaths; Casino, four new cases, one death; Palermo, three new cases, four deaths.

Fourteen new cases and five deaths in the last twenty-four hours, are reported from Constantinople.

LONDON, September 13.—Another death from Asiatic cholera has occurred at Rotherham, in the West Riding of Yorkshire. The physician's report as to the two deaths at Relford, County of Nottingham, confirms the statement previously sent in these dispatches that they were caused by Asiatic cholera. A death that recently occurred at Gansborough is now declared to have been due to the scourge. A death occurred at Leicester Sunday, the symptoms being considered suspicious by the physician attending the case. An examination was made, which resulted in a certification that the death was due to Asiatic cholera.

Letters from the Crimea says that cholera is committing terrible ravages. Hundreds in the province of Taurida are dying daily. The official figures give thirty-eight deaths last week, whereas there were more than thirty deaths in two towns alone. The authorities have forbidden the tolling of bells in order not to cause a panic through the frequency of funerals.

LONDON.—The *Official Gazette* declares London and Liverpool to be suspected of infection with cholera. All vessels from both ports will be inspected rigorously.

*** Have Quarantined.**—The State Board of Health has issued an order that all passengers out of Muncie, Ind., must show certificates of proper vaccination and that their baggage has been disinfected. This is to prevent the spread of small-pox, which is epidemic in Muncie.

Dr. Dewitt C. Patterson of Washington, one of the Trustees of THE JOURNAL, is seriously ill, and at the last meeting of the Board, resolutions were passed by the other members expressive of their sincere regret in learning of his illness, and their earnest wishes for his speedy recovery.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from September 2, 1893, to September 8, 1893.

A board of officers, to consist of Col. JOSEPH C. BAILEY, Asst. Surgeon General; Major LAURENCE DE WITT, Surgeon; and Major HENRY M. CROSBY, Surgeon, is appointed to meet at the call of the president thereof, at San Antonio, Tex., for the examination of such officers as may be ordered before it, with a view of determining their fitness for promotion.

Capt. HENRY S. KIDDER, Asst. Surgeon, will report in person to Col. JOSEPH C. BAILEY, Asst. Surgeon General, president of the examining board appointed to meet at San Antonio, Tex., for examination for promotion.

Capt. MADISON E. TAYLOR, Asst. Surgeon, having been found by an Army retiring board incapacitated for active service, is granted leave of absence until in further orders on account of disability.

Capt. JULIAN M. CARROLL, Asst. Surgeon, is relieved from duty at Ft. D. A. Russell, Wyo., and ordered to Washington Bks., D. C., for duty with the company of instruction of the hospital corps.

First Lieut. ALLEN M. SMITH, Asst. Surgeon U. S. A., is granted leave of absence for four months, to take effect on or about October 25, 1893.

Dr. Henry P. De Forest of Brooklyn, has been appointed Asst. Surgeon of the Thirteenth New York National Guard.

ORIGINAL ARTICLES.

INSANITY AMONG CONVICTS.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY M. V. BALL, M.D.

PHYSICIAN TO THE STATE PENITENTIARY FOR THE EASTERN DISTRICT OF PENNSYLVANIA.

The few cases here presented illustrate some of the types of insanity found among persons convicted of crime.

I do not believe the fact of their being convicts influences the insanity in any way; but because of the conditions under which they have been raised, and the selection practiced by courts, the most degenerate classes find their way into prison and thus come to our notice.

Very often superficial observers accuse this or that mode of imprisonment as predisposing to insanity. As well charge the almshouses with breeding idiots because the mentally defective are found in them.

The separate system of cellular plan, as practiced in the penitentiary for the eastern district of Pennsylvania has been accused of driving men insane, and year after year this charge finds its way into print.

There are insane prisoners in that institution—some sent there because of their insanity; others whose insanity was not recognized before they were admitted, and some who have become insane during their imprisonment. Insanity exists in about the same ratio in other prisons and among the same classes, outside all penal institutions.

When we consider the avenues and factors that lead to insanity—syphilis, chronic alcoholism, hereditary defects and the social history of the great mass of prison population, we wonder that insanity is not more frequent among them.

Case 1.—White male, aged 38, native of Germany. Family history negative. Childhood uneventful. At age of 14 was hit on the head with an iron instrument causing a depression of skull yet visible, and a discharge of pus at the time of the injury. Was arrested in Germany for quarreling and while in prison had an attack of probable mania. Was arrested in New York city for assault and battery and pronounced insane and sent to an asylum at Newark, N. J. His wife obtained his release but he was subsequently returned for abusing her. After the death of his wife in 1889, he had intercourse with his 12-year-old daughter, as he claims while under the influence of liquor. For this crime he is now serving a sentence of five years. He was regarded as insane on admission, and his conduct since has corroborated this opinion. He believes himself Christ, God, a poet; writes Bibles; revises them; makes crowns out of paper; talks fluently, though not incoherently. Has periods of excitement during which he is homicidally inclined.

Case 2.—White male; age 44; native of the United States. Mother committed suicide and he was reared by strangers. Has been arrested six times for larceny, highway robbery and assault and battery, serving in all some eight years in prisons. He is now serving his second term here. While serving his previous sentence here he

attempted suicide by cutting his throat because some of the other prisoners teased him. During his present term he has behaved well—has been constantly in separate confinement—answers questions readily and intelligently; has hallucinations of hearing his neighbors speak ill of him and putting spells on him so that at times he can not eat or sleep. He believes himself to be an executioner and obliged to "desassinate" people when their time comes. He claims that he has put away 3,000 people by striking them on the head or stomach.

He expresses his views as follows: "To kill a man through malice, that is murder; to kill in self-defense is manslaughter, but he is obliged to kill because the court says so." He sleeps well, always turns out his allotted work, says "good day," etc., to his keeper, knows his sentence and when his term expires expects to work on a railroad as brakeman as he has done heretofore.

He is intemperate in liquor and vengery. Eyes staring. No other physical signs noticeable.

Case 3.—White male; aged 23; native of the United States. Mother died of phthisis. No other family history. Has been arrested three times for burglary, serving seven years and is now serving a sentence of five years here. On admission giving evidence of symptoms of phthisis, he was placed in an appropriate ward. He quarreled with two different cell companions, both of whom he accused of attempting to abuse him. He was then placed in separate confinement in another block; this displeased him and he refused to eat; he kept his bed and would not get up; one morning he announced himself as a holy ghost; commanded the keeper to open the cell door and laid on his bed with an ecstatic look and immobile. This continued for a few days when he was sent to the hospital where he promised never to call himself the holy ghost. Cold baths were given him whenever he disobeyed. He ate well, slept well, but at intervals pretended to have religious powers. In a few weeks he seemed perfectly normal, and said he would never attempt such actions again. He was sent back to the ordinary working cells and in a few days broke out again, singing at night time, etc. He was then placed in the coal gang outside where he worked well, and now does miscellaneous work around the corridors apparently well. He attempted to run away one day but was caught, and explained that he was afraid he would be hurt. When questioned about his previous trouble he says he remembers everything; that he was in the habit of abusing himself; that he is nothing but a man; but something in his way of repeating words and a certain absentness at times, together with very much heightened reflexes make me think that he is not simulating. He says that he was always nervous; that he got into crime by running away from home when he was 16 years of age and getting into bad company, and that he can blame no one only himself. Once he attempted to hypnotize a fellow convict and when asked about it said, "It is a gift from heaven." He has attempted sodomy. At first he believed himself drugged, and poisoned and refused medicines.

Case 4.—White male, aged 66; native of the United States. Family history negative. At the age of 8 years had a fracture of the skull which left a depression, but no serious consequences seemed to follow. He worked at various occupations from the time of leaving school at 16 until he was 26 years of age. Upon one occasion while in a saloon a row occurred and he was shot in the throat and shoulder. He recovered after a narrow escape. Afterwards he was obliged to change his residence on account of difficulty with an officer. At the beginning of the recent civil war he began to raise a company but it was not accepted. He tried to enlist but the company was full, but finally succeeded in joining a California regiment, and at the battle of Ball's Bluff was injured in the rectum, from the effects of which he was discharged. Afterwards he re-enlisted and served until the close of the war.

While working on a railroad as a special officer he got into a drunken quarrel and shot two men for which crime he was sentenced to the penitentiary for five years but was pardoned at the expiration of five months. He subsequently fell off a scaffold, broke his nose, crippled his hand and dislocated one patella. After twenty-three years marriage his wife gave birth to her first child and she became insane. He then became intemperate, was placed in an inebriate asylum for a short time and after his release had illegitimate relations with a woman for four months drinking excessively during all this period. The woman was found one day shot, from the effects of which she died. He was convicted of the crime, was sentenced to a term of twelve years in this institution which is now nearly completed. After he had been here six years and was working at carpentering he got an idea he was going to be removed and attempted suicide by twice cutting his throat, splitting his head open with a hatchet and cutting a gash across his arm. These wounds were all healed and he was returned to the carpenter shop, when he again made a suicidal attempt by driving a spike into his temple. When this wound was discovered he said he had fallen on a nail. About two years ago he says the devil came into his head again and he tried to cut a vein in his arm. He was placed in the hospital where he remains. He thinks he hears people talk about him, and worse than all, he hears himself talk about those he likes. A voice within him seems to utter curses against his best friends. Nowhere was he treated so well and yet this voice will talk; but it is only a delusion as no one ever hears him say anything derogatory. He eats and sleeps well; is entirely rational in every way, and I am disposed to believe that his injuries were inflicted with the purpose of exciting sympathy and to prevent his being removed. He now works around the yard and is obedient to orders.

N. B.—Removed back to his own cell lately; he has never referred to his hallucinations, a thing he did daily while in hospital.

Case 5.—White male, aged 36. Father and mother intemperate, and brother a thief. He was sent to the house of correction for assault and battery, and claims to have been arrested thirty times for this offense. He is now serving a sentence of one year here for larceny in breaking the window of a pawn shop, as he says, "to steal." When admitted here he was excited and suffering with acute mania, probably alcoholic in origin. His cell was covered with his own filth; his clothes torn to shreds. Night and day he kept up constant talk in which prayers and curses were jumbled together. He had exaggerated ideas; he was God; he could drink thousands of bottles of beer; he had fifty children, etc. Hypnotics had little effect on him.

This condition continued for several weeks when he was placed at the wheel in the wash house and made to turn the crank, but every now and then he would pick up dirt and eat it or tear his clothes. Gradually, however, he became quieter and more tidy, and now he is well behaved but his exaggerated ideas continue, and at times his eyes fill with tears and he promises everything, and then will instantly change and threaten vengeance. He says his trouble comes from drink and this appetite he attributes to inheritance from his father. His entire illness has lasted about one year.

Case 6.—White male, aged 39. No satisfactory family history. Says his father was hung. He has been arrested three times for entering houses. Has various insane delusions about electricity; believes he is worth millions; does not associate with the other men in the wash house where he is employed, but whenever the opportunity offers walks off and talks to himself. He answers questions only after repeated pressing. Recognizes his crime and knows his sentence and expresses the hope that it will be his last. Was defective on entrance.

Case 7.—White male, aged 27. Native of the United States. Family and previous personal history good. Worked well in prison until five months ago, when his overseer noticed a gradual apathy and disinclination to talk or work. A new cell companion had been given him, and to him he would not speak. He eats very little and will do no work. He lies in bed constantly and when asked what is the matter replies, "I do not know." There was slight rise of temperature, cold extremities, and replies to questions in monosyllables and generally "don't know." Physical examination negative. Urine normal. Tongue coated. He gave his name, age, and complained of pain, but does not know where. Knee reflexes exaggerated; pupils react normal. Was sent to hospital and during the same evening

talked with other convicts about shoemaking but only when drawn out.

The next day he refused food; said it would not go down. Temperature normal. No obstruction in throat and so informed him, when he swallowed as usual. He remains awake at night murmuring to himself. Diagnosis: Stuporous insanity, or so-called primary dementia. Ordered cold baths and abundant light food. The latter he now ate readily. In a few weeks he seemed sufficiently restored to return to work, in fact, asked to do so. Within a few days after returning to work he again relapsed to his former condition, sitting in one place constantly and never speaking. Was readmitted to the hospital and put on light work in the yard, but would not move unless constantly urged. The fear of the bath was sufficient to impel him to many things. His appetite is voracious. He sleeps well; answers only after repeated questioning, and then only yes or no. Has grown fat; reflexes normal; secretions normal. When first admitted to hospital he would allow saliva to gather in his mouth and dribble over his clothes. Later he would constantly spit on the floor and soil his bed, but he is now cleanly. His head is always bent. He never looks at any one. Occasionally he can be made to smile. He promises to do better when the cold baths or wet cups are suggested. There has been but little change in his condition for the past two months. Is serving first sentence here for assault and battery.

Case 8.—Colored male, aged 42. Sister epileptic; he is very ignorant; believes prisoners below him are endeavoring to extract a confession from him and to that end torturing him with electricity. He feels electric sparks going through him and hears voices saying, "Turn it on stronger; make him tell us." His suffering from imaginary torture will occasionally be so great at night that he screams out. No physical ailment can be detected. Moral influences have had some beneficial effect and for weeks he will be apparently well. He works regularly. A partner was given him, but this seemed to have no effect upon his hallucinations. He is serving second sentence for larceny.

Case 9.—White male, age 40. Nativity, England. Family history good. Has been convicted four times for larceny, serving in all six years. Was similarly troubled in his mind while serving a sentence in Canada. While here he believed the food poisoned; spirits came in the walls; he concealed weapons with which he threatened the overseers. He was disciplined and has since been quiet and pleasant. He claims he has no more delusions or hallucinations. He believes he did wrong, and it was proper that he should be punished, but he calls God to aid him, and expresses a wish to die here. He sleeps and eats well and is abundantly nourished.

Case 10.—White male, age 30. Nativity, Austria. Family history negative. At 9 years of age had a serious illness and was unconscious but does not know what the disease was. He is a baker by trade and a sailor by occupation. Seven years ago he was convicted of rape on a child 9 years old, and sentenced to this institution for a term of ten years, which is now nearly completed. About eighteen months ago he announced he was going to die; it had been revealed to him. He stripped off his clothes, refused food, etc. This lasted a short time and he became all right again. The priest says he had noticed evidences of insanity in him on religious subjects. He is one of the best prisoners in the institution. He does the work assigned him regularly; believes he is atoning for his crime and no doubt would become easily disturbed if the subject of religion were broached. He has only shown this one outbreak, and since has acted rationally and has no other delusions or hallucination.

Case 11.—Black male, age 20. Family history good. Early personal history negative. Convicted of breaking in a house. When he had been here eleven months developed acute mania, becoming filthy, noisy and destructive. Was placed in wash house to work and now, after two years, has had no recurrence of the difficulty. His mind seems well balanced and he has no recollection of the symptoms described above.

Case 12.—White male, age 32. Family history negative. Was addicted to intemperance and venery. Convicted of attempting to kill his mistress in a fit of jealousy and sentenced to five years here which he is now serving. After the lapse of eighteen months from his admission his cell companion was discharged, and being left alone he began to make a noise and rave, all of which he remembers. He continued in this condition for three months when he was placed in the hospital in association with other prisoners when his raving stopped. He desired a partner. He accounts

for this malady by attributing it to masturbation which he claims to have practiced two or three times nightly. As soon as he entered the hospital he appeared all right and has continued so up to this time now three years. This was evidently a case of simulation. An element in the case was the effort of friends to obtain a pardon for him.

Case 14.—White male, aged 63. Native of the United States. Grandmother and aunt committed suicide. He is a machinist by trade and had his skull fractured by an accident; was unconscious at the time and his wife would not permit trephining. He showed symptoms of insanity six years ago. Has worked sometimes at his trade and sometimes at other occupations. Had spells of unconsciousness and forgetfulness. He invented a patent and stole tools to complete it and for this was arrested, pronounced insane and sent to an asylum. He escaped and wandered around the country working at odd jobs and finally came to Philadelphia where he was caught in stealing some tools and sent here for seven years for attempting to resist arrest by an officer. On admission was easily moved to tears; could remember nothing; cried constantly; was worried about his wife and children whom he imagined to be starving; gave an assumed name; seems well educated; has a depression in the skull and begs to be operated upon, either to die or get well. Letters from his wife and from the asylum corroborate his statements. He has no apparent delusions. He left the asylum because he thought he was well and wanted to earn a living for his family. His case at times resembles one of cerebral softening.

After he quieted down and was given something to do to occupy his mind he became more rational; wrote letters; made a model of his lock out of wood, and eats and sleeps well. His memory continues impaired. His wife says that when he gets to worrying he has spells of violence, a possible epileptoid condition, and he will leave home and wander around. He is yet very easily excited so that he trembles and can not write.

Case 14.—White male, age 31. Native of the United States. Illegitimate child. No family history obtainable. Mother is very voluble and might be called foolish. He is addicted to intemperance and venery. He was first convicted of larceny in his twelfth year and has since served six terms for similar offenses. Four years ago he was convicted of assault and battery on his wife and sentenced to three years. Two days after the expiration of that sentence he was arrested for a similar crime and upon conviction sent here under a sentence of three years, making his eighth conviction and sentence. He has hallucinations of hearing. People speak about him, and they with his wife are constantly persecuting him. He has hallucinations of sight also. He is easily excited and angered. Eyes staring.

Case 15.—White male, age 53. Engineer by trade. Phthisis on mother's side. Had syphilis twenty-six years ago; was formerly intemperate in habits. He met with an accident during the war in which his skull was fractured. This was followed by one month of delirium and one year of dementia. Since then there has been no noticeable symptoms except that delirium easily occurs when drunk. In a quarrel he struck a friend with his fist and killed him. Pupils are pin hole in size; knee jerks greatly exaggerated. No other physical symptoms. No evidence of any psychological disturbance.

Case 16.—White male, age 34. Loom fixer by trade. Father insane. One sister committed suicide while insane. He has had "general nervous trouble" for the past four years, with illusions at times. Is intemperate in liquor and venery. He struck his aged mother a severe blow for ordering him out of the room. He has a small head; semi-agitated; is very irritable when under the influence of liquor. No evidence of any delusions or hallucinations now.

Case 17.—White male, age 34. Carpenter by trade. Father addicted to drink and had a stroke of paralysis, which took him to the almshouse. He was convicted of patricide and sentenced to ten years. He has tremor of hand; knee jerks greatly exaggerated. Has been nervous for years. When angered he will instantly use any weapon at hand. Is bothered greatly by insomnia. There is no evidence of delusions or hallucinations.

Cases 15, 16 and 17 represent a group that is very interesting and which might be classified as neurotics; not criminal neuropathy as Wood defines a class, but *simple neuropathy*. They are persons whose family history shows crime, or insanity, or intemperance; who have always been fidgety; prob-

ably, as children, "bad tempered" when opposed; who have indulged in liquor to excess; who have not been dominated by any distinct delusions or hallucinations or impulses, but who opposed in a quarrel they can not control themselves, and the first best thing they can grasp is hurled madly at the object of their sudden passion. A moment afterwards they are sorry and curse themselves for their uncontrollable temper.

Often we meet children with such ungovernable passions they are feared by their parents and hated by their friends. No doubt such moments of anger could be traced in the childhood of many "homicides of occasion."

The outburst of ill temper found in the early stages of general paralysis is readily diagnosed from that of the neuropathies, because in the former it is unusual and a change from another condition. In the latter, however, they have been nervous from childhood.

When paralytics commit crimes that are punishable they present so many other phases of their disease that lawyers soon discover it, and they are switched off to the proper asylum.

We find among fifty cases showing mental trouble fourteen were indicted for homicide, or 28 per cent., while in the entire penitentiary population only 9 per cent. are murder cases. (The census statistics of 1890, of all the prisons in the United States gathered by Wines, gives 8.9 per cent. of homicides to the total prison population.) Eight of our fifty cases were convicted of assault with intent to kill, and seven for rape, making a total of twenty-nine or 58 per cent. committed for crimes against persons. Of the entire prison population only 30 per cent. are sent for crimes against persons while 70 per cent. are for crimes against property. Thus our statistics support the opinion that insanity leads more often to crimes against persons than against property. Very seldom does the crime seem to be the direct outcome of insane delusions.

In 40 per cent. of our insanities, ideas of persecution, "Verfolgungs Wahn" is clearly developed.

The prisoner known as specular by his cell companion, tells his overseer some morning that he "should not put any more of that stuff in his food;" he sends for the doctor and claims he is being poisoned; he commences to write letters to various persons, the warden, inspectors, etc. Again he complains about persons occupying neighboring cells speaking of him; they call him obscene names and accuse him of indecent crimes. He abandons work and sits all day in the corner of his cell, speaking only when repeatedly addressed. His bowels are or soon become constipated, but otherwise the prisoner appears well. His cell and person are kept clean. Sometimes he refuses his food for a few days, but is easily persuaded to eat.

In some cases religious ideas are intermingled. He may believe himself possessed of the holy spirit; God has commanded him not to eat. Hallucinations sometimes combine themselves with delusions about his sentence. He imagines his time has expired and he is restrained from going out. Letters are withheld from him, and a pardon awaits him in the office.

Sleep is variable. Some rest soundly, while others are kept awake all night by their delusions. According to their own explanations, "electrical appliances

keep them awake" or "persons come through the windows and awaken them," etc.

The hallucinations may each be only of short duration, recurring at varying intervals. They may be constantly present, but interfering so little with the daily vocation that the prisoner eats, sleeps and performs all tasks without interruption, and his defect is only disclosed by questioning.

The hallucinations may disappear entirely and not return during the balance of his term, and only reappear in some form when he returns to serve another term as a re-convict.

And just here occurs the difficulty of at once recognizing simulation. If one who presents such manifestations of mental disturbance is placed on extra diet, excused from work and receives other privileges given the sick, if he is maligning he will attempt the same deceit whenever he enters a prison. And even men who were not simulating the first time may attempt the deceit subsequently on account of the privileges.

There are very few forms of insanity in which punishment and reward are not understood.

There is at present in this penitentiary a man who is serving a life sentence for murder, committed as a sequence of his insanity, who was always considered "cranky" by the people who knew him. He is noisy, filthy and incoherent, yet were I to place him in a hospital cell with others he would be quiet and neat. Only at times will he become very talkative. This has been tried several times with him with the same result. He is not left permanently in the hospital for fear of injury to others.

I am acquainted with no possible test to detect all simulation. When prisoners will feign to obtain slight favors while in confinement, how much greater is the incentive when on trial for life or liberty.

Case 18.—White male, age 43. Native of Ireland. Family history negative. Deprived of father at early age. Came to this country with his mother and located in New York city. Began to run streets and at 9 years of age was placed in house of refuge. At the end of a year in that institution he was bound out on a farm, ran away and returned to New York city, where he became a newsboy. When 12 years of age he followed a company of soldiers destined for New Orleans and left them at Cairo and began operations as a hotel thief, stealing clothes, etc., and thus working his way back to New York, where he became the associate of a bad crowd. At 14 years of age he was sentenced to a year in the New Jersey penitentiary, and three months after the expiration of this term he was returned under a four years' sentence for burglary. The night following his release from this term he robbed a guest at a hotel, enlisted in the navy, went by sea to California and there deserted and worked his way East. He enlisted in the regular army, fought all through the Modoc war, deserted, went to San Francisco and resumed his occupation of hotel thief. He was finally caught and sentenced to four years in the California State Prison. While there was witness to the murder of a prisoner by his room mate. This brought delusions and he began to imagine people were trying to kill him. After his discharge these delusions vanished. He resumed his old occupation and worked his way back to New York at the expense of the hotels en route. Here he was convicted of another crime and sentenced to Sing Sing for four years. In prison his delusions returned and were treated without avail. Upon his discharge they again disappeared, and he resumed occupations working the hotels until he reached Chicago, where he was sentenced to four years in the Joliet Penitentiary. The delusions returned and continued throughout his confinement. Upon his release he worked his way to Philadelphia, and caught in the act of stealing at the Lafayette Hotel, shot the watchman, and received a sentence of ten years here, which he is now serving. He is a quiet man, well behaved here, eats and sleeps well, and rational in all

his conversation. He does not claim to have been impelled by some uncontrollable force to steal, but did so because that life pleased him.

There is another prisoner here who escaped from the Auburn Insane Asylum for convicts, who was sentenced here for breaking into a jewelry store. While in the county prison he manifested signs of mania, but here he was rational until one day he had some trouble with his knitting machine, and in his passion wrecked it. When reprimanded he said he would do such a thing whenever it bothered him, and threatened any one who attempted to prevent him; that was the way he did in other prisons and that was the way he proposed to do here; he was no one's slave. He was disciplined and made to understand that such conduct was not permitted here, and since, there is not a more civil or industrious convict than he in our population. There is no evidence of insanity. He has spent most of his life in various prisons for burglary. Like the previous man noted he follows this occupation as a matter of choice.

But, in reality, simulation is rare here. More frequently does true insanity go undetected throughout the trial and is only discovered by the prison physician or keeper.

That the crimes of the insane bear no relation to their insanity is a well known fact easily established.

A man who has hallucinations or delusions of persecution might logically be supposed to commit an assault on the person he imagined as offending, but in fact they are often common thieves and are repeatedly convicted of burglary or larceny. As a companion of one such aptly remarked, "he hasn't sand enough to kill a fly."

The crimes against persons are often committed in a drunken quarrel—a man is killed without the slightest premeditation, a rape accomplished or attempted under the influence of liquor, etc.

Probably the crimes resulting from insane delusions or hallucinations take their perpetrators to insane asylums, but the record of such crimes is not large.

In this connection I am impelled to refer to the usual practice of the courts in the treatment of offenders whether sane or insane—the moral responsibility—"does the man know the right or wrongness of his act," is the usual test.

When a person commits an act contrary to the laws of the country a jury is empaneled to decide as to his guilt and all the facts in the case, and when the question is raised, these are made to include the sanity or insanity of the defendant, and what a judge, jury and lawyers take weeks often to decide, an ignorant fellow is asked to do offhand.

This question of absolute right or wrong is both a broad and intricate one. It involves each man's idea of what is right or wrong and that depends almost wholly upon his education and surrounding influences. If this be true is not the man of few social advantages less responsible than those with many? May not an act be right for one individual and wrong for another? Or at least wrong for one and not culpably wrong for the other? And so the worst criminals be less responsible?

How many years is it since we have ceased to punish people for their beliefs?

The common opinion (at least as it finds expression in print) is that justice is not administered in a spirit of vengeance. The aim is only to deter, protect and reform. If this be the real motive, why inquire about the moral responsibility? Is not protection needed as much from the criminal acts of the insane or mentally defective as from the mentally strong?

Beccaria says crimes are only to be measured by the injury done to society, and our modern penologists are approaching the same conclusion. Paul Dubuissin (*Archives de l'Anthropologie Criminelle*, Vol. vii, No. 38), says: "When we will only consult the social utility in our treatment of criminals then the great question between crime and responsibility will cease. Then will arise in each case not, Is he responsible, but is he dangerous to society? Not, Does he know the difference between good and evil, but is he of more evil than good to society?"

It matters not, then, whether we believe with Lombroso that all professional criminals are diseased and therefore irresponsible, or whether the criminal be morally insane, a born criminal, an habitual criminal, an idiot or defective of any class. If he is unsocial, society should be as much protected from his acts as she seeks to be against cholera, leprosy or any other corrupting or dangerous or unsafe influence. And the more dangerous the more protection.

Is the criminal an insane person, or do we find insanity more prevalent among criminals than among honest folks?

The answer to this question depends upon our interpretation of crime and honesty.

As we have no real measure for right we can not with entire accuracy say one man is honest and another dishonest. Every man on one side of the iron bars is not a criminal, and every man on the other side an honest man. Diogenes would have just as much need for his lantern to-day as in the time of Alexander the Great.

It is *conviction* that makes a man a criminal in public esteem, not *detection*. How many are there among us who have not some time in their lives committed an act that was punishable under the law? and had it been enforced would have sent us to the reformatory or prison, and thus by a simple application of the law, without reference to its violation branding us throughout our future lives as criminals. I stole an apple when I was a youngster. Many a boy has received a year's sentence for less and obtained his degree in a house of refuge. Because I was not caught I am supposed to be honest. The other lad is a *criminal*.

The smartness of the lawyer keeps many a guilty defendant out of prison. The theory is that every man is equal before the law. Practically we know this to be a fiction. When the machine is in good working order with a batch of poor and friendless victims on hand, they are "railroaded" to prison with so little an attempt at legal defense as to amount to a farce.

In view of the self-evident unevenness and partiality in the administration of law, it is impossible to draw the line between the criminal and the non-criminal classes so as to compare the diseases peculiar to each.

A CASE OF SO-CALLED MORAL INSANITY.

Case 19.—White male, age 23. Nativity, United States. One sister reported as having chorea and another puerperal insanity.

When eight years old was sent to the house of refuge for running away from home. After a residence there for thirteen months he was returned to his home. At the expiration of another year was arrested for larceny and being

declared insane was sent to an asylum and from there to an institution for defective children, and from the latter finally ran away. He stole from his parents and was generally so incorrigible that he was placed in the Norristown Asylum as morally insane. At the expiration of two years he was discharged and at once returned to his old habits. In 1886 was again arrested for stealing from his parents and readmitted to an insane asylum from which he was discharged at the end of a year by direction of the Board of Lunacy. In 1890 he was convicted of larceny and sent to the Huntington Reformatory, from which institution he was transferred here for incorrigibility. He says he is addicted to intemperance, opium, onanism and venery and seems proud of his record. His mother can do nothing with him and in the neighborhood of his home he is a common nuisance. The first day here he tried to obtain opium through complaining of cramps as he claims to have succeeded in doing in other institutions. He failed here, however, and has had no returns of cramps. He maligned epileptic fits. These were promptly cured by the cold water douche. He went through the entire list of troubles to obtain special privileges or escape work, with the regularity of a professional. Failing in every attempt and through the assistance of persistent but harmless discipline he has finally been brought into fair submission. He has been exhibited as a living example of moral insanity. When asked questions before a class of students he would purposely give false and outrageous answers to keep up his reputation. His crime history has been obtained and thoroughly established by relatives and acquaintances. He is short and fleshy, head brachycephalic, eyes small, teeth irregular, boyish feminine appearance. He is very cowardly and fawning—never abusive or angry.

Is this lad insane? Is it moral blindness? Was his home training defective? These are questions which no one can satisfactorily answer, and yet society needs to be protected from such a class.

He belongs to a class that is rapidly increasing and especially in the large centers of population. They are the "incorrigibles" of reformatories and as such are transferred to prisons and inducted into a career of professional criminality which they follow until death. The reformatory can not or does not reclaim them; the prison has no terror for them. If their energies and genius could be diverted into some useful occupation they might become beneficial members of society.

The question whether criminality is due to mental defect, remains unsolved.

Mandley says: "The criminal class constitutes a degenerate or morbid variety of mankind marked by peculiar low physical and mental characteristics."

By an artificial selection such as is practiced in our police courts, the man who can afford to obtain able attorneys, or pay fines, or by his talents avoids detection, or by many of the other fortunate or practical known avenues escapes conviction. Then as a rule only the poorest, most ignorant and lowest classes are sent to prison, the exceptions being the rare occasion of a great popular clamor where some victim must be taken from the higher class, but these are limited to the very smallest number demanded to satisfy the outcry. A prison population so collected must of necessity be degenerate from every point of view.

Does insanity appear more frequently in prisons than in communities outside? Authorities in former times have all answered in the affirmative. Can this

answer be accepted as entirely true? Were these convicts insane before they reached the prison? Did their insanity lead them into crime?

Is it insanity or is it simulation? Semal finds insanity much more prevalent among those outside than those inside prisons. Sir Matthew Hale is quoted as saying: "Habitual felons suffer from a degree of partial insanity." This means nothing, as there is no complete insanity. Dr. Macdonald of Auburn, in his twenty-third annual report "believes crime to influence the insanities and to constitute them as a distinct class." He remarks on the general absence of expressed delusions, generally coherent in conversations, perform their allotted tasks, display wonderful combinations of shrewdness and cunning in their efforts to escape.

If we compare the lower orders of men in the community at large with those in prison, the proportion of insane in each would not differ much.

The trouble with all our statistics on the subject is that they are one-sided. We must divide society into classes, according to wealth, ability and position, as Chas. Booth has done in his "Life and Labor of the People."

Class "A" in prison must be compared with class "A" outside before any reasonable conclusions are warranted.

We know that insanity does sometimes cause persons to commit crime, but there are many insane who do not commit crime, and there are many criminals who are not insane.

Masoin, at the Anthropological Congress held in Belgium, gave the following differences between the criminal and the insane act: the diseased kill for the sake of the deed—rob for the sake of robbing, without any other aim. The criminal acts out of covetousness or hatred. After the act he seeks to conceal himself; the alien does not.

The crime calms the insane. It troubles the criminal.

When we will recognize that "every society deserves the criminals it has," and we will endeavor to correct the evils that in a large part cause crime, and treat our malefactors not with a spirit of vengeance, not with a visitation of justice, not as sinners but simply as obstructionists, whom society must place under restraint or remove to a place where they can be of service instead of hindrance, then only will the penal question reach a solution.

Has a man stolen my pocket book two years in prison will not return it to me; time can not measure the injury done me or the suffering caused the prisoner. To one man, ten days will cause as much anguish as ten years to another.

See how childish our present mode of justice; a man commits 100 burglaries and is caught; he is only charged with two; is sentenced to five years imprisonment. His term is served; he is caught stealing a watch and receives two years. He again returns to burglary, and after awhile is caught and is given another sentence of a few years, and so ad infinitum, ten, eleven sentences, each time a trial, each time efforts to detect him, and the numerous times he wholly escapes detection. What would be thought of the suggestion that a chronic maniac be sent to an insane asylum for one year and then released unconditionally; then after he had killed some one, again returned for a definite term of one or more years?

The danger to society alone should be considered

and the professional criminal placed in "durance vile" until cured, if that result is possible; or permanently if the danger to society is ineradicable, and this wholly as a protection to society and irrespective of his sanity or insanity, his moral responsibility or irresponsibility, his reformation or punishment.

CHAIRMAN—I think Dr. Ball is to be congratulated on doing what has been done too little in this country, namely, working in the prisons for facts in reference to mental diseases, instead of having issued from the officials of prisons and others in authority general statements about matters of this kind. This, I think, is a sort of work which will do for criminology what men have done for other forms of mental disease outside of prisons.

DR. F. P. NORRERY of Jacksonville, Ill.—I have met with quite a number of these cases in the Illinois Hospital for the Insane. It is a rule in the Illinois institution, or was until the inauguration of the criminal hospital for the insane, that all criminals found to be insane should be sent to the State Hospital. As a result, we got all cases belonging to the county or district in which the hospital was. I found that quite a number of these cases were not chargeable with criminal responsibility, and it is just from that standpoint that I would like to speak—cases of paranoia in which the delusions were not thoroughly settled, but probably did exist prior to the commitment of the crime, which after conviction and sentence to the hospital or to the penitentiary developed. I have in mind two cases; one convicted of horse stealing and sentenced to five years, another case convicted of larceny. Another case I might mention is a case of homicide, life sentence; one of these cases was a marked case of paranoia and is now in the Central Hospital for the Insane. The patient's delusions are thoroughly systematized and all of a religious nature; he believing that he is Elijah, and his inspirations come through the rocks, etc., and daily he is engaged in his preparation of prophecies. The other case is a case of general paralysis and the patient died after having gone through the regular course. His insanity was not recognized as general paralysis or in fact as insanity for over a year after his sentence, when his maniacal attacks increased and he became a subject of considerable anxiety to the prison officials. The other case is a paranoiac under life sentence; and he is one of those individuals who is being poisoned by the guards and is having noxious gases thrown into his room by unseen forces, and who also has telephonic communication with the devil and his hordes daily. As a result, you can imagine that he can make life miserable for all about him, which he has done since he came to the institution. It was on this account that he was placed in the Hospital for the Insane. It is evident that the attention given to mental diseases in the prisons of our State has been sadly neglected, and it is to be remarked also, that in the paper that accompanied those cases from the prison officials, every form of mental disease is set down as dementia, duration unknown, no symptoms given and no history at all, and all that we can get is probably from the guard who accompanies them. The appointment of the prison physician is largely political; his attention to details in regard to mental disease is very slight, and all the history we can get is from the guard and from the patient himself.

DR. J. G. KIERMAN of Chicago—We have had too little on this subject, especially from American alienists outside of Dr. Ball. I remember some communications of Dr. Carlos Macdonald of New York, based on his results in the Auburn Lunatic Asylum and in part in the penitentiary. In a general way he found the same features of insanity among the inmates, such as delusions, ideas about being poisoned, etc.,

as has been mentioned; but it seems to me that a number of the cases that the doctor has reported might belong to a good many other categories; for instance, one case which is classified as stuporous insanity might possibly be epilepsy. There were no convulsive attacks to be sure, but their occurrence is not necessary in epileptics, there being perhaps but one in a long period and recurrent stupor taking their place. With regard to the frequency of insanity in prisons, I would state that on one occasion I went through the reports of the Joliet Penitentiary, and discovered that the proportion sent from Joliet to the various asylums was twelve times the ordinary proportion in the State according to State statistics. A number of those cases came under my observation at the Cook County institution. They had gone to the State institution, their term had expired and they had been transferred to the hospital. There was one case in particular which illustrates the point that is often ignored, that underneath a primary hallucination may run a secondary delusion which may impel a man to crime. This man had a delusion about witchcraft; he was a negro and a paranoiac and his delusions were based on certain experiments in mesmerism which he had seen performed in his boyhood; and it is a fact that he stole in order to get placed in the penitentiary to escape mesmeric persecution.

Another fact, in which I was very much interested, was that the penitentiary officials had reverted to the old procedure of Louré. As the majority remember, he used to treat the insane as follows: argue with them to show them their peculiar absurdity and delusion and hallucination, and then proceed to douche them; and he undoubtedly checked the exhibition of the delusions of a large number of his patients. In a few cases the inhibitions were sufficiently strong to control the patient, but the great majority of his cases when followed up were found to be rendered even more persistent and dangerous than before. Another point raised by the doctor which I think does not quite deserve the credit given it, is the attempted differentiation between the insane and criminal. The insane do things with the same motive as the criminal. You will find insane people stealing from each other, and recognizing that the insane man knows what he is about in that thing. You will find that in patients in the wards they will make that distinction themselves between stealing that is delusional and that which is not. Furthermore, it is stated that the insane have not accomplices. Here very often you have a central figure, a paranoiac, a principal, and he has a number of accomplices, some of whom may be sane and some insane of a weaker type. Take for instance the celebrated religious homicide that occurred in Massachusetts. The son of Freeman was ill-balanced and so was his wife, but around them were a number of sane Second Adventists, and some affected with mild paranoia.

With regard to the test of insanity in Illinois, we have no test, strictly speaking, other than the essential test of the common law based on each case. For instance, if you raise the question of insanity in Illinois, the State must overcome the presumption of insanity and must prove the prisoner insane beyond a reasonable doubt. Furthermore, even a prosecuting attorney would not attempt to raise the right or wrong test, pure and simple; the insanity must have overridden the reason and judgment; that is the test in Illinois. Of course, as Dr. Norbury has stated, the people in charge of the penitentiaries are decidedly careless in their examination, study, history and treatment of these cases. One of the physicians in the penitentiary on the witness stand recently did not know the name of the inferior maxillary bone. He was a graduate of Harvard, had turned Hahnemannian and was in charge of the Joliet Penitentiary in the interest of a certain clique. He is now at the head of a homeopathic asylum in California.

Paretic dementia was spoken of. I remember that New York three cases came to Ward's Island Hospital. They had been a year in the penitentiary and repeatedly punished for dirty habits, and one of them an old laborer, had stolen socks and shirts in plain view of everybody in a store. The boldness made it plainly insanity. We found his back criss-crossed with lancing. In the interests of society I think it is best to adopt the view of considering the criminal of the habitual type as a chronic lunatic and to shut him up for life. I remember the case of an expeditious man who lost a portion of the bone in his head from an accident. The traumatism resulted in delusion with occasional periods of excitement. His wife gave him quinine on one occasion and got him quieted when the police broke into his room, but the insane man knocked the policeman down with a hatchet, grabbed the policeman's clothes, put his wife's hat on his head and paraded the street with a club. He was arrested, taken to the station house, tried, and the jury gave him three years, and the very intelligent judge took off one year on account of the injury to his head. The man went to the penitentiary three months and then went to the insane hospital. The absurdity of sending such a person to the penitentiary is evident. The whole system needs remodeling, but it can be done without any change in the common law which must furnish the basis of all change.

DR. BALL.—I would like to see the chronic criminal shut up for life, but I do not think it would be well to regard him as a lunatic in order to accomplish that, unless you can prove his insanity. As far as epileptics are concerned, I would say that I have as yet very few who have shown any signs of their epilepsy in prison. They might have been epileptics, but because of the quiet life they led in prison they never had any convulsions there. It is usually the fact that epilepsy has a great deal to do with crime.

HEMIPARAPLEGIA; WITH REPORT OF A CASE COMPLETELY RECOVERED AFTER ONE YEAR'S DURATION.

Read before the Section of Neurology and Medical Jurisprudence at the Forty-fourth Annual Meeting of the American Medical Association.

BY L. HARRISON METTLER, A.M., M.D.

CHICAGO.

In certain lesions of the spinal cord, the prospects of recovery are so much more hopeful from surgical interference than from medical treatment, that an exact diagnosis is of paramount importance. Hence every ray of light, however feeble it may be, that illuminates the question of spinal cord localization, should be most carefully cherished. Our knowledge of the motor centers of the cord is already sufficiently exact to guide the surgeon in his operations, but the precise limitations of the sensory areas are matters still of much uncertainty. A great deal has been accomplished towards increasing our information in this respect by Oppenheim, Westphal, Rosenthal, Eulenberg, Ross, Mills, Osler, Church, and especially Thorburn. According to the general consensus of opinion to-day, the decussations of the sensory and motor tracts are such that a lateral focal lesion anywhere below the cervical enlargement gives rise to a *hemiparaplegia*, with paralysis upon one side of the body and anaesthesia upon the other. Every instance of an anomalous presentation of this classical picture must be possessed of unique interest, hence I beg to present the following case, which has seemed to me to be worthy of special study:

case. 24. D., a bright, cultured girl 20 years of age and residing in the western part of Pennsylvania, was brought to me Oct. 5, 1890, by Dr. C. J. Stein. The following history was narrated to me by the patient herself in the presence of the doctor and her elder sister: On the morning of Dec. 25, 1889, while walking along the street, she accidentally stepped upon a loose coal-hole cover and fell in such a manner that the left leg passed down into the coal-chute while the right was extended out over the pavement. She fell completely out with her whole weight. Unconsciousness at once resulted, and on account of the free use of narcotics by her medical attendants, she was not fully cognizant of her surroundings until a week after the accident. In the meanwhile the hip joint was found to have been dislocated and was immediately reduced. There was a considerable hemorrhage from the vagina, and in some way indistinctly described, she was torn. Shortly after the accident the left limb began to swell, became extremely painful and was completely paralyzed. Poultries and hot applications were employed. The fever continued high and with it there was excruciating pain at the back of the head. A week later the swelling of the limb entirely disappeared. Six weeks after the accident, the faradic current was employed locally to the paralyzed muscles without any improvement. In March, three months after the accident, the swelling of the limb reappeared. At this time there was no local sweating, no glossing of the skin, no formation of blisters or sores. This was the last time that the leg swelled. During the course of the year, the right arm enlarged somewhat and became cold and cyanosed. This occurred some five or six times. At no time were there any symptoms of a similar character in the left arm or right leg. There were no circutary pains, no eye disturbances, no dysphagia, no dyspepsia, no dyspnoea. The bowels remained unaffected, with the exception of a few small bleeding piles which appeared immediately after and seemed to be one of the direct results of the fall. The rectal sphincter was very slightly if at all affected. The sphincter of the bladder was much weakened. Severe metrorrhagia occurred some five or six times, and during the entire year there was a profuse leucorrhoea which for a time contained considerable pus. Prior to the accident menstruation had always been painful and scanty, but now had become very much more so. Micturition also produced severe pain. The urine was never voided in normal quantity, but frequently contained a small amount of blood and sediment. At times violent pains shot along the spinal column, especially in the lumbar and lower dorsal regions; while a continuous intense pain was felt in the occipital region of the head. This latter pain was almost constantly present, but on alternate days became so exceedingly unbearable that the patient was obliged to take to her bed and make free use of anodynes and narcotics.

Three weeks before the patient was brought to me, a brilliant stroke of lightning flashed close beside the room wherein she was seated. She experienced a most peculiar sensation or "kind of rush" up the spine into the head. She fell, became unconscious for a time and continued to be delirious for several days after. For a long while she said she could feel a kind of repetition of the shock about every third or fourth day. Usually the sensation died out in ten or twelve hours. When I saw her she was still subject to intense constricting headaches. These seemed to strike from the back of the head forward to the temples, were always worse in wet weather, and as a rule lasted about twelve hours. Sometimes the face became puffed and pale, while the eyes would be directed inwards. Two weeks after the accident the patient first noticed for herself that her left leg was completely paralyzed and anæsthetic. No improvement had occurred in this respect during the course of the year. So much for the history of the case.

Upon examination I found the eyesight and hearing both good. The grasp of the hands was normal and the same in both. In the right leg the patella reflex, ankle-clonus, muscular movements and sensation were all normal. In the left leg they were all completely abolished. The line of beginning anæsthesia corresponded quite sharply with that of Poupert's ligament in front, the crest of the left ilium and a line drawn transversely across the left half of the back on a level with the crest of the ilium or fourth lumbar spine. Above this line there was considerable hyperæsthesia. The limb was well developed,

warm to the touch in its upper part, and exhibited the natural color of health. Both the cutaneous and muscular sense were entirely wanting. The deep insertion of a needle into the tissues, the strongest electric currents as well as simple contact with the skin, were absolutely unperceived. So thoroughly did I test for sensation that the possibility of simulation was completely eliminated. A similar examination of the opposite leg and of the two arms revealed nothing abnormal in regard to motion or sensation. Severe pressure along the course of the left crural and sciatic nerves gave no indication of pain. There was no atrophy, as actual measurement showed both limbs to be of the same size. With the use of faradism, a mild primary current produced slow but decided muscular contractions, while the secondary current gave rise to more marked muscular movements. The galvanic current produced the usual normal responses. I could detect no indication of the reaction of degeneration. The electrical examination was not, however, as complete as I would like to have made it, as the patient was suffering from considerable pain in the spine and I did not care to distress her further. The distal circulation was slow, and as a result the leg and foot were cold and cyanotic. The whole spinal column was so exceedingly sensitive to the touch that its examination was not so satisfactory as could have been desired. In the region of the lower lumbar vertebrae it was unusually tender, so that the patient winced and screamed with the pain each time I gently pressed the lumbar spines. Between the third and fourth lumbar vertebrae I could distinguish on the left side a small, hard nodule about the size of a pea which was especially painful. The distress and general nervous excitement of the patient prevented my determination at that time of the nature of this swelling. In the vicinity of the sacrum and coccyx the pain upon pressure was quite unbearable.

As a result of this somewhat incomplete examination, I diagnosticated the case as one of incipient meningo-mylitis, with the meningitis as the more pronounced feature at the maximum intensity of the disease focalized on the left side of the lumbar cord. I imagined that at the time of the accident there had been a hemorrhage within the spinal column, either in the lumbar region or elsewhere, and that some of the blood had gravitated and formed an irritative clot which in conjunction with the attending inflammatory process was compressing and constricting certain nerve roots from the left side of the cord. With this conception of the case, I recommended a vigorous daily counter irritation of the entire spine, the administration of mercury (blue mass guarded by opium) to the point of ptyalism, the use of the mild faradic current to the paralyzed muscles, and the employment of cod liver oil by local injection. The treatment was commenced Oct. 5, 1890. About a month later, Nov. 7, or nearly eleven months after the accident and onset of the paralysis, the patient arose from her chair and walked with as much ease apparently as she would have done in perfect health. She stated that a few days prior to my last visit she suddenly felt a kind of tingling and burning sensation, as though the leg had been "asleep," and were recovering, and that this was immediately followed by a complete restoration of its movement and sensation. Hyperæsthesia, I found, had replaced the anæsthesia and though it tired the patient

quickly to use her limbs. Its power of motion was not to have been completely regained. The 12-28-89. Sensation was noticed at the same time with a sharp sensation up and down the entire length of the sacral cord. I found the tenderness of the vertebrae almost entirely gone so that the patient could stand quite vigorous blows upon the back, except in the lumbar region where it was still some what sensitive. From this time on she ate and slept better and the bleeding of the hemorrhoids ceased. On Nov. 1, Dr. Steim wrote me as follows: "Patient is steadily improving and is quite as strong as ever she was." On April 28, 1892, I received this note from the Doctor. "I am glad to inform you that Mrs. S. (she had become married by this time) has never had a single symptom of the old trouble since you saw her. In fact her health generally since then has been almost perfect." Again during the summer of last year the Doctor wrote me: "The recovery has been perfect and the patient has been as strong, if not indeed stronger than ever before in her life, with the exception of typhoid pneumonia over a year ago."

The unilateral distribution of the anesthesia and paralysis in this case indicates, of course, a unilateral lesion. The presence of the motor and sensory paralysis upon the same side would suggest a lesion outside of the cord proper. The absence of any girdle pain or pronounced alteration of the sphincter functions, and of atrophy of the muscles establishes the non-involvement of the gray matter of the cord. The upper border of the anesthetic area limits the upper border of the lesion to the level of the first lumbar segment. The tenderness of the spine, the fever and other constitutional symptoms resulted of course from the meningitis, which was probably a mere extension of the inflammatory process from the lumbar region upwards. The traumatic origin of the paralysis is extremely indicative of a fecal hemorrhage and the presence of an irritative clot would be an all-sufficient reason for the inflammation of the membranes. The hemorrhage was probably subarachnoid. The transitory symptoms which arose during the course of the year in conjunction with the upper regions of the cord may have been due to a number of smaller hemorrhages of which the blood may have gravitated and so produced a large irritative clot along the line of the lumbar segments and in the meshes of the cauda equina. The chief difficulty in this explanation, however, is the completeness of the anesthesia from the very beginning of the paralysis: for such a sudden and complete anesthesia usually follows a lesion in the substance of the cord itself or complete severance of the nerve roots. When nerve roots are compressed by hemorrhagic clots or meningeal adhesions it is more customary for the anesthesia and paralysis to be preceded by pain, hyperaesthesia, paresthesia and spasm. Furthermore, with anesthesia dependent upon destruction of the posterior nerve roots, there is generally very decided atrophy of the corresponding muscles, especially if the lesion involve the root ganglion or that part of the root external to the ganglion.

It must be admitted that there are certain features about this case strongly suggestive of hysterical hemiparaplegia. They are for instance the sex and age of the patient, the location of the paralysis (hysterical paralysis being most frequent in the left leg) the absence of any considerable atrophy, the apparent preservation of the rectal with but slight involve-

ment of the 2-3-4-5-6-7-8-9-10-11-12 segments of the parasympathetic system, the absence of the peculiar dissociation of the motor and sensory correspondences, the slow development of the limitations of anesthesia, the absence of pain. Against the hysterical hypothesis, however, stand the traumatic origin of the motor and sensory paralysis, the absence of an hysterical reaction, simple in duration this or any previous period of the patient's life, the prolonged duration of the paralysis and anesthesia without the slightest modification, the absence of the hysterical temperament, the completeness of the anesthesia and the perfect insensibility of the nerves to the strongest electric currents, the hyperaesthetic zone just above the level of the anesthetic area and the complete restoration without the slightest subsequent reappearance of any of the old symptoms. Furthermore the upper limit of the anesthesia posteriorly corresponded with a horizontal line drawn across the back on a level with the fourth lumbar vertebra, and not with the line of hysterical paraplegia which Charcot says, "follows the insertion of the muscle of the buttocks exclusive of a V-shaped area over the sacrum."

In the *American Journal of the Medical Sciences* for July, 1892 Starr reports a case (No. 5) possessing many points of similarity with our own. Briefly stated, the patient was a woman, 28 years of age, who was well until May, 1889, when after a day of fatigue she was suddenly seized with severe pain in the sacral region and in the back of both thighs, with retention of urine and feces and with a sensation of numbness over the lower sacral region, perineum and vagina. The urine and feces were moved with much difficulty. The sphincter was contracted on the finger. The knee-jerks were exaggerated. The plantar and gluteal reflexes were normal, and there was no tendency to bedsores, no tenderness of the back, no girdle sensation nor anesthesia of the legs. When examined again in Feb. 1890, there was beginning muscular weakness in the left leg and a diminished response to faradism, without atrophy. There was still some pain in the back and in the left leg constantly but more especially in the left ilioinguinal region. There was still no girdle sensation, spinal tenderness or bedsores. The area of total anesthesia had increased. There was slight impairment of the tactile sensation on the outer side of the leg below the knee and on the back of the thigh from the anesthetic area downwards. The case was not so far advanced as ours, but in the association of its symptoms closely resembled it. The diagnosis of Starr was that of a hemorrhage into the conus medullaris and lower sacral segments of the cord. He suggested that this hemorrhage had lighted up a chronic meningomyelitis and as this advanced slowly upwards, it had increased the symptoms.

Starr and Lloyd's case (No. 11) in the same paper, was one of compression of the cauda equina producing a localized paralysis and limited anesthesia in the right leg. There was a fracture of the lumbar vertebra, followed immediately by a paralysis and indefinite area of anesthesia in the right leg. A year later there was marked deformity at the third lumbar vertebra, paralysis with atrophy, reaction of degeneration of most of the muscles of the right leg, anesthesia down the back and outer side of the same limb. In view of the diagnosis of compression of the cauda equina at the third lumbar level, Dr. Lloyd open-

rated and removed the second and third lumbar spines and laminae with ultimate recovery of the patient. The point of significance in this case is the association of the anaesthesia and paralysis, which is explained here by the limitation of the lesion to the cauda since the spinal cord proper terminates at the first lumbar vertebra. The absence of the sphincter symptoms would exclude involvement of the corresponding nerve centers, which Starr finds from two of his cases to be located in the "lower two segments of the cord," a fact which has been confirmed by autopsies in the cases of Kirchhoff, Westphal, Oppenheim and Herter, and in the cases of Rosenthal, Bernhardt, Eulenberg, Mills and Huber. It is always difficult, except in fracture cases, to differentiate lesions of the cauda from those of the cord; and Starr takes the position that it is "questionable whether, except in cases of fracture below the first lumbar vertebra with displacement of the vertebrae any sharp line of distinction between cord and cauda lesions should be attempted." It is to be hoped, however, that some day our knowledge may permit us to make such a differentiation.

In connection with the case I have reported, the question arises as to the possibility of there being a unilateral paralysis and anaesthesia in the same limb, as a result of a single unilateral lesion of the cord. In other words, Is there such a thing as a true hemiparaplegia produced by a focal lesion in which the paralysis and anaesthesia are not crossed? The textbooks almost universally answer this question in the negative. Ranney¹ says: "The muscles below the seat of the lesion are paralyzed on the side of the body corresponding to the exciting cause and the skin is sometimes rendered hyperæsthetic; while the integument of the side opposite the lesion is deprived of sensibility." In his "Lectures on the Nervous System," he furthermore most emphatically states that "should symptoms of anaesthesia appear upon the side where the motor paralysis is present, you may regard it as conclusive evidence that the exciting lesion is progressing and the opposite lateral half of the cord is being involved to a greater or less extent." Seguin² writes that "hemiparaplegia is a rare variety in which one lower extremity is paralyzed while the other is anaesthetic."

Mills³ says that "motor paralysis occurs in the leg of the same side and anaesthesia in the trunk and leg of the opposite side." So authority after authority might be quoted, all stating the same truth. They insist upon the crossed nature of the symptoms. The sensory fibers, after passing through the posterior nerve roots, enter the gray matter of the posterior cornua and at once cross to the opposite side of the cord through the posterior commissure and then continue their course upward to the cerebral cortex. In the upper part of the cord the fibers decussate almost immediately after they enter the posterior cornua but farther down the cord we find them running for a short distance more or less vertically in the side of the cord and in company with the corresponding nerve roots before they pass to the opposite side. In other words, the decussations are relatively higher than the corresponding nerve roots the farther we proceed down the cord. In the

words of Gowers,⁴ "The decussation of the sensory tract is not immediate but occurs somewhat above the entrance of the nerves." This, I believe, is of some importance in the diagnosis of our case; for as Gowers again remarks, "A lesion in one side of the lumbar enlargement often affects sensation on the same side as motion because it damages the sensory path before it has crossed." In our case I can not think the anaesthesia was due merely to compression of the nerve roots by the meningeal trouble, because it came on so early and suddenly and was not preceded by the usual hyperæsthesia and initiative signs of local meningitis. In fact, the whole set of meningeal symptoms seems to have been of later development. Nor can I think that the posterior nerve roots supplying the anaesthetic area were themselves torn or injured in such a way as to be alone responsible for the loss of sensibility, because the anaesthesia lasted too long to be so quickly recovered from. Torn nerve roots are not usually restored in a few weeks' time by mere external counter irritation and the administration of mercury. I assume, therefore, that the sensory tracts must have been injured somewhere near the periphery of the cord, and that this must have been before the tracts which transmit tactile impressions were separated from those which carry the sensations of pain and temperature since all forms of sensibility were abolished from the anaesthetic area.

According to the most recently constructed tables of segmental spinal localizations, the lesions could not have extended higher than the first lumbar segment. The paralysis and anaesthesia stopped quite abruptly at Poupart's ligament anteriorly and the upper part of the buttock posteriorly. There were no girdle pains whatever, either of the body or the limb, to enable me to determine the level of the lesion more accurately. If the original trouble were a subarachnoid hemorrhage, as I fancy it must have been, the blood may have gravitated to the lower part of the spinal column and involved the fibers of the cauda without doing any special damage to that structure beyond compressing it. A clot may readily have formed on the left side of the cord opposite the lumbosacral region, there exerted a pressure sufficiently deleterious to prevent the transmission of the motor and sensory impulses in the corresponding tracts as they passed along near the circumference of the cord, and also to have lighted up a meningitis which gradually extended along the whole column and even implicated to a slight degree the membranes covering the brain especially in the occipital region. Such an explanation is the most reasonable to my mind and harmonizes most satisfactorily some of the discordant symptoms of the case. If such be the correct explanation, the case indicates that we may have a hemiparaplegia, especially from a lesion in the lower part of the cord, in which the anaesthesia and paralysis appear upon the same side of the body. Further investigations are needed, however, upon this point, though I feel sure that the textbooks are somewhat too dogmatic in asserting that in all cases hemiparaplegia is a paralysis of one-half of the lower part of the body with anaesthesia of the opposite half.

WHAT SHOULD CONSTITUTE LEGAL RESPONSIBILITY, IN THE MEDICAL SENSE, IN INSANITY?

Read before the section of Neurology and Medical Jurisprudence at the Forty-fourth Annual Meeting of the American Medical Association.

BY LANDON CARTER GRAY, M.D.

PROFESSOR OF NERVOUS AND MENTAL DISEASES IN THE STATE UNIVERSITY OF NEW YORK POLYCLINIC.

It is high time that we medical men should impress upon lawyers the fact that the question of legal responsibility in insanity should not be determined by laws, but by facts. As it is, the belief of English and American jurists is that which is embodied in the statutes of almost all of the States, to the effect that knowing the nature and the quality of an act and its consequences should be taken as a full test. As every one in this room will know who is acquainted with the insane, this dictum is worse than ridiculous, for it is false, as there are very few forms of insanity in which the patient is not fully aware of the nature, quality and consequences of an act which he or she may commit. Out of this definition of a legal responsibility has grown the legal belief that a person is possessed of testamentary capacity when he or she can talk in a sufficiently intelligent way to evidence a knowledge of the nature, quality and consequences of the will which he or she may be making. Indeed, so ill-defined is the definition of testamentary capacity that I have frequently suggested to my legal friends that the greatest certainty of having a will admitted to probate would be to establish the insanity of the testator or testatrix. Let us briefly examine the facts, not the statute law, about insane patients.

All the types of insanity that have been demarcated up to the present time can be classified by:

1. The moods.
2. The presence of hallucinations.
3. The presence of delusions.
4. The coexistence of the neuroses.
5. The coexistence of organic disease of the brain.
6. Traumatic causation.
7. Causation from excessive use of narcotics.
8. The mental disturbances occurring induced by disease of non-nervous viscera.

Mania and melancholia present as their basic symptoms alterations of mood; the former being an exaggeration in slighter or greater degree of good spirits, and the latter presenting the converse. When there are hallucinations as the chief symptom around which all the others cluster, there is hallucinatory insanity. A persistent delusional condition, at first consisting of delusions of persecution, to which in the course of time are added delusions of self-exaltation, constitutes that type of insanity to which has arbitrarily been given in latter days the name of paranoia, formerly designated delusional insanity. Mag-nan, it should be said by-the-by, maintains that in many cases of this type the delusion of persecution is never succeeded by that of self-exaltation or grandeur. Such neuroses as hysteria and epilepsy lend a peculiar imprint to mental disturbances occurring in the course of them. These insanities, whose pathology is yet but dimly understood, are happily embraced by the Germans under the generic term of the psycho-neuroses, to distinguish them from the mental disturbances which occur in the course of such organic diseases of the brain as hemorrhage,

thrombosis, embolism, meningitis, tumors, intracranial syphilis, and that slow, remittent, insidious encephalitis which is known as parietic dementia or general paresis, and which is characterized by the commingling of characteristic mental symptoms with physical ones. Insanity of traumatic causation is usually an insanity due to organic cerebral disease produced by trauma, or to epilepsy from the same cause. We are all familiar with the mental disturbances from alcoholism, cocaineism, morphinism or chloralism. I have but little faith in the frequency of so-called reflex insanities, i.e., those produced by slight lesions of non-nervous organs, but no one will attempt to deny that mental disease can occur from the widespread vascular, textural and nervous derangements of nephritis, pyeluria, hepatitis, typhoid, peritonitis or septicemia.

Of all these varieties of mental disease, the ones that most frequently give rise to medico-legal questions are paranoia, mania, melancholia, general paresis and the insanities arising from the excessive use of narcotics. In paranoia the mental condition is, as has been said, a delusional one; generally at first of persecution, to which in the course of time is added another of self-exaltation or so-called grandeur. But these delusions are perfectly logical, and the memory and the reasoning powers are intact. In mania there is chiefly an alteration of mood, so that the patient seems more vivacious than usual, and in the subacute form this exhalation may be so slight as not to rise above the level of high spirits, while in many instances delusions and hallucinations are not present, and in most there is the same preservation of the reasoning powers and the memory as in paranoia. In melancholia the alteration of mood is that of depression, but in a vast number of cases, constituting the bulk of mental diseases observed in general practice, this depression is so evanescent and slight as not to be greater than that caused by indigestion, a disagreeable bit of news, an unpleasant emotion, and a thousand and one other disturbing factors in life; while in melancholia, as in mania and paranoia, the reasoning powers and the memory may not be at all affected. In the early stages of general paresis and in its remissions the element of stupidity is so slight that it can often only be detected by an observer made keen by experience. In the mental alterations caused by undue indulgence in narcotics there may only be present some hallucination, some delusion or some unbalanced judgment that can not be evidenced except by observation of the patient through days, perhaps weeks. In all these forms of insanity, therefore, it is absurd to test the patient's knowledge of the nature, quality and consequences of an act by merely questioning him. For instance, Dougherty, the so-called lover of Mary Anderson, murdered a young Dr. Lloyd of the Flatbush asylum, because he believed that Lloyd was one of the agents of a system of legal procedure that had done him grave injustice, and he was proceeding to murder a supreme court justice and about a dozen State and county commissioners of charities whom he thought to be agents of the same legal machinery, when he was fortunately arrested. All this murderous action had arisen from his delusion that Mary Anderson loved him and that the world had con-

*In all these types of insanity hallucinations, illusions, delusions and alterations of mood may occur, but it is the predominance of one or the other of these symptoms that is the basis of classification.

spired to prevent his going to her. Yet when this man was tried for murder, he insisted on taking the witness stand himself, and stating that he knew perfectly the difference between right and wrong, and the nature, quality and consequences of the act that he was doing when he shot Dr. Lloyd. The jury found him insane; but there was so much doubt in the public mind that a commission was appointed, of which I was a member, and he was again adjudged a lunatic. Judged by his general intelligence—indeed, by his own statements—this man understood well what he was doing. Nevertheless, it was evident to every one that his delusions so warped his mind that he did not realize, in the true meaning of the word, what he was doing. Nor do I believe that any insane person has a true realization of his acts. Never mind how small the flaw may be in his mental machinery, it may be quite sufficient to warp the mind. The law clings tenaciously to the old idea of lucid intervals; but alienists nowadays no longer believe in them, and the imperfect science of a former day probably mistook remissions for them. No one can catalogue the human mind, except in a very general way. So far as we have been able to analyze it clinically, however, it may be said to consist of sensations received by a conscious intelligence in a way that experience has shown to be normal to the human being, as well as of actions springing from this intelligent recognition of sensations. If the moods are altered, as in mania and melancholia, there can be no intelligent recognition of sensations. If the sensations are faulty, giving rise to what are technically known as hallucinations and illusions, the intelligence is corrupted by false news traveling in over the perverted nerves from the various tissues of the body. If there are delusions, the intelligence, in proportion to its intelligence, is the sport of these delusions. If the intelligence itself is confused, causing what we call stupidity, who can venture to prophesy what the mental outcome will be? If erratic actions arise from diseased brain cells receiving normal or perverted sensations, these very actions are evidence of a warped mind. I could make this short recital of instances much longer if I were to go into all the clinical proof at my command of how a seemingly partial mental defect is really a general one.

But I think that you will agree with me that the only safe test of the legal and testamentary responsibility of a man lies in an answer to the simple question: Is he insane? If he is, he is not legally responsible for his acts, nor has he a testamentary capacity. Nor should this question be determined by questions put by lawyers, by fine-spun metaphysical definitions of mental aberration or by evidence of seemingly intelligent acts and motives, but rather by examinations made by physicians competent to decide whether the man in question is suffering from one of the recognized types of mental disease. When a physician testifies that a man is sick with some disease affecting a non-nervous organ, no lawyer would dare to raise a Homeric roar of laughter by asking him for a general definition of sickness, instead of having him localize the disease and then make him state the usual symptoms of this malady. Is it not true that the same common sense should be applied to mental diseases? I think so, most assuredly.

LEO KERNY. It seems to me that Dr. Gray's strictures are much more applicable to many of the eastern States

and perhaps a few of the western, than to all. Now in Illinois, although the practice has slightly departed from the decision enunciated in New Hampshire, and which is practically the outcome of the old common law before the ecclesiastical lawyers got to fixing notions about responsibility, the principle still holds that each case is tried on its merits. In the next place the State must prove beyond a reasonable doubt that the man is insane, if the defense raises even a suspicion of insanity. In New York the right and wrong test was swung into the code under the influence of David Dudley Field, with the old notion of deterring the insane from crime. It so happened that David Dudley Field himself had a relative who committed a crime and under that same test was sent illegally to an insane hospital. Even in New England we find judges on the bench applying the strict letter of the code in trying such cases as that of a woman who has killed her child with the full knowledge of the consequences of the act. It seems to me that all these cases can safely be left in a great degree to evolution. The more you attempt to express matters in the statute the more you tend to crystallize them and interfere with the due course of things. The tendency is directly opposite from what is usually assumed. The proper course is to deal with each case on its merits and not to lay down any general rule, and that is the old doctrine of the common law. Even old Sir Matthew Hale's divisions of insanity are correct, except when he is influenced by the ecclesiastical law notion of responsibility, when he gets sadly twisted.

DR. FRANK R. FRY—I would like to ask what the Doctor means by having established a suspicion of insanity in a legal way, so that the case might be presented on that basis. I am not familiar with what the method is in the State of Illinois.

DR. H. M. MOYER—The practice in Illinois is under the common law, and it seems to me from a careful study of the statutes of other States and those States like New York that have codes, that the practice that holds under the common law is far preferable in these cases. The proceeding in Illinois is substantially this: a person that is charged with crime is indicted. Then it becomes the duty of the State in the first instance after indictment when the person is called upon to plead, to accept the plea of not guilty, if insanity is to be the defense. The State then goes on and makes its own case as to the crime. Of course that is perfunctory where it is practically admitted that a crime has been committed. Then the defense comes in, if there is no defense on the merits, if insanity alone is rested upon, to prove the mental condition of the patient. What is meant by the suspicion raised? It is this: no matter how much or how little is raised as to the mental condition of the patient it must be overcome by the State; and the rule of the law that is given to the jury is that the State shall make out in rebuttal after the defense is put in, and prove the person sane beyond a reasonable doubt; which means that every scintilla of evidence tending to show that the patient is insane must be overcome by proof. We have tests that are propounded and used, and sometimes they go into our instructions, but the common law is so construed in that State that the tests are practically inoperative, because there is always an instruction asked on the part of the defendant, taking all the facts of the law into consideration, does the jury find that the reasonable doubt is in favor of the prisoner. That brings it down to a matter of the jury entirely. I will say regarding Dr. Gray's paper that it seems to me that he is a little in error on one point. He says that insanity if present should absolve a man from the consequences of his act and should not entitle him to testamentary capacity. The rule of common law as most States

give it, is that there is a different degree of mental aberration to absolve from responsibility for a criminal act, and that it will permit a man to will his property. The rule of the law in determining whether a person has testamentary capacity or not is, Did the person know and comprehend the matter, in which he intended his property to descend and to whom, if he comprehended these two factors it has generally been held that he has testamentary capacity. Certainly, I admit of a degree of mental defect far greater than would excuse a person for committing a crime. I think that we shall never reach any better basis than that of the common law, although there are faults that can be found with it in some respects. It is to be remembered as the darkness of mental disease settles down on a man's mind it does so gradually; there is the beginning of twilight settling down into hopeless dementia and all stages between those, and there must be an arbitrary division fixed somewhere, and I do not think that arbitrary division can be fixed by medical men or by lawyers. Nobody can fix it, because it is the same thing as after sunset; when the sun goes down there is a period of all shades of twilight into absolute darkness. No one can say where day leaves off and night begins absolutely. So in mental disease; some such flexible rule as is adopted by the common law I believe to be as near perfection as we shall ever get in dealing with the matter of insanity as a defense in crime.

DR. L. C. GRAY—I did not know that the State of Illinois had a law so entirely different from that of New York, but certainly the textbooks of law do not give any such rule as seems to be current in Illinois, and the test taken altogether of the American States is the test of the individual knowing the difference between right and wrong measured in the consciousness of the act. There are many absurd laws which judges will attempt to get around by permitting a laxity in their application, but as long as those absurd laws remain on the statute book, some martinet of the law may make you follow the hard and fast line. Whatever the practice may be, the statute law can always distort the practice. The fact is that in the majority of our States the old test of responsibility of right and wrong and the knowledge of the nature and consequences of the act remains; we in New York are constantly asked to solve that question by the testimony put at our disposal and it leads to all sorts of fraud and injustice, whereas a much simpler test would be simply, Is the man insane? It is no answer to say to that, that we do not know all the forms of insanity. We can make out the majority of cases that come before the courts. It is better to have some test than not to have any at all, as we have now, even though that test is not a perfect one.

I should disagree with Dr. Moyer in regard to the gradual obliteration of the mental faculties and the ultimate passage into dementia; because there are different forms of insanity, acute and subacute and chronic, and their onset may therefore be very sudden, or on the contrary gradual. The onset of transitory frenzy is very rapid indeed. Then again a great many forms of insanity like paranoia do not pass into dementia, and a great many of the cases of mania and melancholia have no inherent tendency toward dementia, so that I do not think that that line of argument will exactly prove to be the safe one. I do not think that any man's mind that is affected by disease is a safe mind to be left to dispose of his own goods and chattels. The statute law or any law made by sane minds, can do better than the mind of any insane man no matter how slightly affected, and you can not tell with all the myriad reflexes and connecting causes, how much of a given act or of a given opinion has been made up by diseased action and diseased reflexes. It is utterly impossible for any man to unravel that knot, and taking the common sense of it, is it not much safer to

trust the disposition of that property to the sane mind which is thought over by competent and educated laymen and which is so good that many able lawyers would as prefer to leave their property to be distributed by the statute law, rather than to say that the criminal must have a right to disinherit her nearest relatives, as was the case in the case of Buffalo Mrs. Richard Linton, who disinherited every legitimate heir, to encourage a pseudo-scientist and religiously giving her property to a society for all sorts of wild purposes, leaving her heirs in absolute poverty. It is no use to discuss what would abstractly be the best, but what is in the majority of cases an improvement on the present system, which is no system at all, and which was simply a wretched system when originally proposed, and a disgrace to our present civilization, inasmuch as it takes no ground whatever as to what has been done in psychiatry for the last fifty years.

LEGAL CRITICISM OF MEDICAL EXPERT EVIDENCE.

Read before the Section of Neurology and Medical Jurisprudence at the Forty-fourth Annual Meeting of The American Medical Association.

BY CLARK GAYEN, M.D.

(CHICAGO, ILL.)

A recent writer in the *Columbian Late Times* somewhat intemperately characterizes medical expert testimony thus: "Of all the cant that is canted in this canting world expert medical cant is the most pernicious. Of all species of evidence offered in a court of justice, none, not even the testimony of the accused, when a witness on his own behalf is more freighted with suspicion than is the evidence of the medical expert." And quoting Lord Campbell he adds: "They come with such a bias on their minds to support the cause in which they are embarked that hardly any weight should be given to their evidence." The writer then goes on to say that the medical expert in his first estate was a formidable ally of justice, but that the corruptions of the world have demoralized him. "These doctors," says he, "are of the earth, earthly, and their virtue, if not an unknown quantity is flagrantly insufficient in quality." He charges our profession with a vast amount of "very gaudy and unembarrassed lying," and believes the average doctor to be possessed of such an exalted opinion of his own accomplishments, and such a corresponding contempt for antagonistic views as to seriously cripple his judgment. "The serene Olympian" in the opinion of our author, "mounts the witness stand with a chilling and withering hauteur, a composure and touch-me-notishness that belong only to the elect." This intemperate philippic against expert evidence has recently passed around the newspapers and the echo is heard in multitudinous editorials on the subject.

"Doctors," says one, "seem to regard their profession in such cases much as lawyers do theirs. They are expected to use their knowledge and skill as lawyers do theirs to aid in the detection or acquittal of the accused. The result is the sacredness of expert testimony. It is hardly more valuable than the assertions of the attornays." Nor are these criticisms confined to recent times, for the newspapers and legal journals, no less authoritatively than Justice Gray of the Supreme Court of the United States said in an opinion written many years ago: "Opposite opinions of persons professing to be

experts may be obtained to any amount, wasting the time and wearying the patience of the court and perplexing instead of elucidating the questions involved in the issue." Chief Justice Chapman of Massachusetts may also be quoted as saying that "experts might be found to testify to any theory however absurd," and the learned Chief Justice Redfield of Vermont, author of the best treatise on wills extant says: "Experts are beginning to be regarded much in the light of hired advocates, and their testimony as nothing more than a studied argument in favor of the side for which they are called." Justice Davis of the Supreme Court of Maine went farther than the others, however, when he said: "If there is any kind of testimony that is not only of no value, but even worse than that, it is that of medical experts." With all this weight of very learned testimony against him we might reasonably conclude, that the case of the medical expert witness was effectually disposed of. We still find him, however, though somewhat disfigured yet an important factor in the various litigations that arise. There can not transpire a business transaction of any kind, an act civil, or criminal, of which the courts have jurisdiction but may involve some question demanding the attendance of the medical witness. Criticisms such as I have quoted from bench and press are not, however without foundation in fact. Some to be sure are grounded in a purely ignorant and asinine dislike of another profession. Some due to the bitterness of defeat. Corporation attorneys, no doubt feel themselves often aggrieved and justified in doubting both the honesty and value of much so-called medical expert testimony. Let us look at the causes underlying these conditions and ascertain if possible what are potential on our side, and what active on the side of the legal profession, to bring about this unhappy state of mind in our brother profession and lay upon ours this stigma. The first and perhaps most potent cause lies with the attorney himself. He has a case—perhaps unprepared both in respect to his knowledge of the case and a sufficiency of evidence. He casts about for some bright medical man to assist him. I am afraid he does not always care most to know how unimpeachable is the man he selects. What he wants is help. Honest help if he can get it—if not, help. He wants some one to help him make out his case, which usually means that he has a mark set up and he wants some medical man to swear at it. This matter of the oath is possibly seen from somewhat different points of view by the lawyer and the doctor. Theoretically the oath is to the lawyer a sort of fetish. In all his books and lectures, it has been enough to say "under oath" to express to his mind the highest degree of certainty and solemnity. I doubt if the physician and layman has any adequate conception of the feeling inspired in the breast of the lawyer by the term "under oath." But in some other respects the law in practice does not maintain so high an ideal of professional morals and conduct. It is not generally regarded to be to the lawyer's discredit that he resort to almost any means of winning his case. In legal practice that is constantly done which would make even the doctor shudder for the welfare of the soul of his professional brother in the law. It may be that the great and solemn phrase, "under oath" is not often enough uttered in the hearing of the student of medicine. It may be that he has not in the language of the

Buddhist, "gone into the forest," and seriously meditated what it is to be a witness under oath, but certain it is that he has not been able to see such a vast difference between telling a lie and swearing a lie. He that does the one, will find a way to do the other. When the doctor is on the witness stand, however, the lawyer (on the other side of the case) experiences a sudden expansion of his conception of the gravity and importance of strict adherence to the naked truth. But when the witness is his, the lawyer is too apt to become willing for him to strain any part of his conscience that will help the case. If the doctor is weak enough, he will be thus used again and again, but the very attorney that uses him will cherish a contempt for him. The solemnity of the oath should not be undervalued nor its importance as a safeguard in evidence be lightly considered. But the truth is the truth and at all times most sacred. "Every place a temple" to truth and justice. In the large majority of cases involving medical, surgical or psychological questions the attorneys are merely "crammed" for the case. In the very nature of things this must be so, for it is manifestly impossible for any mere lawyer to have other than a very partial view of the questions involved. He may have acquired knowledge, but he can not have acquired that experience which vitalizes knowledge. It is oftentimes very laughable to realize how partial this view is. Only the fact that the opposing counsel is equally ignorant and the jury still more unenlightened keeps the case from breaking down. I have sat through a trial for manslaughter and heard a bandying back and forth of medical and surgical terms by the opposing counsel that would have kept a medical college in a roar. But with this partial view the lawyer sets up a theory of the case for the poor doctor to work to, and he is expected to help it on whether it would have been his view or not if left to himself. The course chosen, everything must bend to it, everything must be done to help it on, and everything suppressed that will in any manner retard. The trial of the case then becomes a mere contest of wit in adducing and suppressing evidence. Of course this is all wrong and no one knows it so well as the well informed lawyer. It is not common sense, much less common justice. Any intelligent member of the bar will tell you that as at present conducted, the trial of a cause involving a medico-legal question is a mere farce, as compared with the trial of a cause involving a pure question of the law. The reason is simple. The lawyers trying the case understand the questions of law involved and it is Greek to Greek. But they neither know nor understand questions in medicine, surgery, psychology or toxicology. This great fault in our jurisprudence is probably in the main due to the jury system which we have not yet outgrown, and which we are not likely to outgrow for some time to come, notwithstanding the fact that no country in Europe has a jury but England. Another cause is the desire of some lawyers to pose before John Smith as a man who knows everything and to hear John remark that he (the lawyer) knows more medicine than all the doctors. Of course John knows. I believe it will be found an invariable rule that the greater the lawyer the more will he seek and value assistance by those specially trained and informed. The lawyer that merely aims to pose before Smith and expects to win his case by hook or by

crook needs little counsel. It takes a fair sized lawyer to realize that he doesn't know it all and is merely making a fool of himself when he attempts to utilize knowledge of which he has only a mere smattering. The condition referred to can be corrected only by a change in the statutes of the several States relating to the selection and calling of experts. The expert should be selected by the court from lists presented by the counsel, as advisory to it, and wholly with reference to his special knowledge of the question involved, which question should be submitted after the evidence is all in, in the form of one or more hypothetical questions based upon all the evidence. "Opinions on the case" should not be tolerated in any form. They are a plain invasion of the province of the court and jury. We should not, however, conclude that the trouble lies wholly with the law or the lawyer. A large part lies with us and in our faulty systems of medical education. We educate the student in medicine, surgery, bacteriology, pathology, etc., and forget the all important fact that he is to become a *citizen* of a community and that great and peculiar responsibilities resulting out of his professional duties and relations are to be laid upon him by the law. The very first case to which he may be called may involve a grave legal responsibility. It may be a case of murder or poisoning or involve a question of mental competency or responsibility. Nearly every medical college has a so-called chair of medical jurisprudence, but what does it teach? It usually repeats the mummery of some textbook of the science, merely rehearsing in a weak way what has been better taught in other departments by teachers specially qualified. The instruction is uninteresting to the student and valueless. What should be taught are the special facts of medico-legal science, not taught elsewhere, and the legal duties and responsibilities of the practitioner in his triple relation of *citizen, practitioner of medicine and expert*. In short he should be given a forecast of the legal experiences he is about to encounter in the many and varied relations upon which he is about to enter. If he practices at all he must come into contact with law in some manner. This is not a kind of practice he can choose or let alone. He should therefore be especially and carefully taught his responsibilities and duties under the law. He should be taught to know when he is placing himself in a position that will or may make him a witness, and his eyes should be opened to the things he should see and note to make him a reliable and useful witness. He should also know how to be a witness—how to prepare and demean himself, that he may not be disconcerted by the ordeal or reflect discredit upon himself and his profession. He should know that to be frankly truthful, to be calm, self contained, direct and plain in his statements, simple and non-technical in his language, avoiding pomposity and high sounding phrases is to be a good witness and that the converse is to be an ass. Being untaught in these important practical matters he goeth forth as a lamb for the slaughter. I have known a middle-aged physician filling a high position, nearly ruined professionally and an exceptionally well-educated young physician driven out of a city by the want of the knowledge of which I am speaking. That students go forth unequipped in this regard is not their fault. Twelve years of teaching both law students and medical students has

taught me that law students are always interested to know something of medical science, and medical students eager to know that part of the law which concerns them. Another cause of the disrespect of medical expert evidence is the common custom of participating both as counsel and witness in the trial. This, too, is the mistake of the lawyer. He knows better. The doctor does not. A lawyer shuns the witness stand and especially in a case in which he is counsel. It is universally conceded to be bad practice for counsel to testify and important evidence will often be sacrificed rather than violate this rule. Only in extreme cases is it countenanced. But the lawyer not only permits, but encourages the physician to do this very thing—act as a witness and sit by as counsel with the effect of impairing the confidence and respect of court, jury and public in him and in his testimony. It is a practice to be condemned in no uncertain terms. Another grave source of impairment of confidence is the fact that there is a large and growing class of medical men who pose as professional witnesses—expert swearers, so to speak. Men who are tempted by the publicity and the emoluments to frequently participate in trials as experts, even where they are not specially qualified to be experts either by learning or experience. The courts themselves are to blame for this. It is within the discretion of the court whether or not a given witness is expert in respect to the particular question involved. The adjudications are very satisfactory on this point and only need to be lived up to. The legal rule and definition of expert is "one instructed by experience." (Bouvier.) To be competent the individual must be in some way peculiarly qualified to speak on the subject. (3 Bosworths, N. Y. 7.) The fact of special skill must be established or witness rejected. (Ordronaux, 126.) A court may hear evidence to satisfy itself that a witness is really what he assumes to be before admitting him to testify. (6 Rand, 704—12 Alb. 648—1 Munn, 125.) It is often said that the medical profession is narrow, both in its scope and tendency—that the doctor gets rutted and never knows or thinks anything else than medicine and each year grows narrower. I believe this to be in the main unfounded, but in respect to knowledge of the law, which every man is presumed to know, it is true. It is not to the discredit of the lawyer that he knows many things other than the law. Why should it be to the discredit of the doctor that he knows something besides medicine? Are we not too modest in this respect? We should not forget that some of the greatest lawyers this country has produced were first doctors. The late Justice Miller, of the Supreme Court of the United States and Judge Dillon are examples. May we not do something to dissipate the idea that we of the medical profession are not to look beyond the horizon of our own calling?

DR. J. G. KUERNAN—There are two or three points with which I agree and others in which I dissent from Dr. Gapen. There is a certain class of lawyers including criminal lawyers who are exceedingly high, while others are about as low down as possible. That class of lawyers does not, as Dr. Gapen has stated, think the less of a man because he lies. I have known a specimen of that stamp denounce every doctor who appeared against him, as venal, even though he had approached every one of those doctors and attempted to retain him in his case. Furthermore, it is a growing practice among a certain liberal set of criminal

lawyers to form their theory through the aid of a physician in a given case. The physician forms a theory of a case on the facts stated by the lawyer, and the testimony agrees generally much more thoroughly with the theory so formed than with the hit-or-miss method usually employed. That was the case with the medico-legal issues arising in the Cronin matter. In that case the attorneys consulted a physician who never appeared in the case and who made up the minor theories on which the blood question and the other questions were afterwards proven, and every one of the questions drawn up by him were laid before the experts afterwards. With regard to the proposed remedies by the courts, I would say that it seems to me that the true remedy has been suggested by Dr. Gapen, namely, instruction in our colleges in the first place; that in criminal cases every circumstance tending to prove innocence must be taken into account, and furthermore everything must be construed in the light of innocence, and guilt proven beyond reasonable doubt. We find every day, physicians considering certain cases as exceptional and therefore not taking them into account, but swearing positively to a certain set of facts to which there are exceptions. On the other hand, the point should be brought out that the question is one of preponderance of evidence merely in civil cases, and instruction should be given in that line as well as in criminal cases and the distinction clearly shown. True medical jurisprudence is really not taught in our colleges, but in the place of it the Gradgrind method is used of pouring in mere facts.

THE CHAIRMAN—I think many of the reader's points are well taken; still I do not believe that some of his remedies are practical. It is a frequently made suggestion, that the trouble with reference to expert testimony and the evils connected therewith, could be overcome by making the experts the advisers of the court. The method suggested by Dr. Gapen is one; others have been suggested; but in the main they are on the same principle. It has been suggested to have official court experts. A very considerable experience in medico-legal matters leads me to believe that this plan would not work any better than the present except, perhaps, occasionally; at least, I am doubtful of it, and I believe as Dr. Kiernan has said, that probably in Europe they are finding it somewhat of a failure. It would be impossible for court experts to give opinions in an open jury trial, for or against a man, without the party accused being allowed full opportunity for expert and every other sort of defense. Otherwise, it would be taking away the rights of the individual, and simply would result after a time in most of the cases that the court expert would be submitted to the same sort of examination and cross-examination as anybody else, and with this additional difficulty in many cases that the court expert would be a political or personal or some other sort of obnoxious appointment; nor would the difficulty be removed by allowing the judges to call in in special cases a court expert. I do not see how we could get around the difficulty in this way, although it has often been suggested. I think I understood the doctor to say that opinion should not be tolerated.

DR. GAVEN—I used the expression, "opinion on the case," and I used it technically; not in the ordinary sense.

DR. KIERNAN—I understood that you meant hypothetical opinion.

DR. GAVEN—No, no.

CHAIRMAN—Do I understand you to refer to the opinion that experts are called upon to give in court?

DR. GAVEN—On that point you agree entirely with me. I do not say that an opinion should not be entertained by the expert. An opinion is entirely proper, but an "opinion on the case" in law is a technical expression; if the expert

states what his opinion is about the case, then he puts himself in the position of the jury.

CHAIRMAN—As I understand it, the expert or witness will testify as to facts that come within his knowledge, in an examination of an individual, and he gives his opinion on the facts which he has studied himself, or his medical opinion on the facts which are stated in a hypothetical question or in some other way; he gives no opinion upon responsibility, for instance, in a case of insanity. He does not assume the function of the court or the jury, but he gives an opinion upon the facts he has learned in investigation, and an opinion upon a hypothetical question; that is he gives an expert opinion upon it, and it seems to me perhaps the doctor and I are agreed upon that matter.

I fully agree with him in regard to teaching medical jurisprudence in our institutions, and I think with Dr. Kiernan that the true solution of this problem like many others must be in the advance of education, and every other method of attempted improvement in these matters seems to me will fail. As to the medical witness acting as counsel, I believe that very often properly and usefully, he acts as adviser to the attorney on the side that he happens to be retained for. As Dr. Kiernan said it is a common practice, and I do not see any objection to it, for the witness and the lawyer to go carefully over the case in order to see whether or not the witness will testify. If he finds in going over the case that he does not agree with the gentleman who wishes to call him he refuses to testify, and in the same spirit he can, if he does agree, assist in the preparation of the case. I agree with him, however, in reference to the injurious influence on the case which the appearance and particularly the manner in which a medical man sometimes appears in court assisting counsel. I have had some experience in that and I have seen others in this position. I avoid it wherever possible. Lawyers sometimes insist on being assisted in the examination of witnesses. My own experience teaches me that with the jury particularly, and I have no doubt with the judge in many cases, this often acts against the case very much, and it would be a much better plan in the vast majority of cases for the witness to have nothing to do with the counsel in court except upon the witness stand. I do not see anything morally wrong or legally improper in his giving assistance if he gives it in the proper spirit. Now as to courts excluding experts. I think it would be a very difficult matter in many cases for courts to say, and in many cases it would be very easy; but I remember only once in many trials seeing the court exclude a medical witness as not being competent to testify. That was in a case of a man in Philadelphia who certainly was incompetent and who testified in a well known case there that he had made three examinations of the person who was on trial, a woman; and the district attorney in cross-examination asked him what these three examinations were that he had made; whereupon he calmly stated that he had made a digital examination, a general examination and a speculum examination at the same time of the patient. This man was ruled out.

DR. J. E. EMERSON—I think that the doctor has stated some of the difficulties in the way of successful expert evidence but, as it seems to me, aside from the ignorance of lawyers of medicine, a great deal is due to the personal character of the witness, his inability to express in terse brief language exactly what he means, so that he says a little more or a little less than he should; and, at the same time, his fearfulness of admitting ignorance is a great drawback to him. In my observation and that of several of my friends who have been on the stand and who are well qualified as physicians to treat such cases, when they appear on the stand make very poor experts, simply from a hesitation to admit ignorance and from inability to express concisely

just what they mean. In regard to one point, of the witness acting as counsel, perhaps I misapprehend exactly the point, but it has been my observation that in many instances questions can be suggested to the lawyer by the expert witness which bring out the real merits of the case and which can not be brought out or will not be brought out in any other way. It may be said that that is not acting as counsel, but simply to suggest questions. I have a case in mind where a witness who went on the stand was asked by the opposing counsel if he was assisting counsel; he said, no, but he was requested by the lawyer to suggest questions to bring out the real merits and true facts of the case. I can recall a case where the expert suggested such questions, where the questions all hung on whether the patient was epileptic or not; whether the homicide was committed during an attack of epilepsy or not. The questions put by the medical expert through the lawyer essentially decided the whole case on its merits. As regards experts giving an opinion in the case, while I know it is a legal maxim that legal experts should not be allowed to give an opinion in a case, yet I have in mind two cases that occurred in the courts in Michigan where the judge permitted exactly that thing to be done. The question was put, "Have you heard all the testimony in this case?" Answer, "Yes." Q. "What is your opinion from this testimony as to the mental condition of this patient?" And he was allowed to answer the question. At the same time the Supreme Court of Michigan has ruled that such questions must be put in the hypothetical form.

DR. J. G. KIERNAN—I merely wish to make one statement that may avoid some little discussion in regard to a question that I raised. It is a matter of record that the French Psychological Association came within three votes of urging the adoption of the Anglo-Saxon expert system in France and the same is true of the German Psychiatric Association, although by not quite so close a vote. We find decisions of courts varying as to what constitutes an expert, and we find also that various tests are applied by different courts in varying conditions and that frequently opposite results are met with.

DR. WILLIAM THOMAS BISHOP—One phase of the medical witness which has not been brought out is of great importance. As a general thing the expert would take care of himself, if medical jurisprudence were taught more fully and in a better manner than at present. For instance, in the case of an accident on a railroad, if the physician knew just exactly how to make the examination and how to get the information when he first saw the patient, that would be a matter of the most vital importance in cases of injury which may result in death; also in cases of alteration, of abortion, etc., if physicians were educated up to getting what would be legal testimony, that would be worth a great deal. But there is one misfortune about the medical witness and that is he often puts himself out of the way to get on the witness stand; he thinks it a smart thing to put himself on exhibition. Another smart thing that he often does is to put himself in a position to antagonize some other practitioner. I have seen a good deal of that. My father was a criminal lawyer and I was raised in his office; he wanted me to be a lawyer, but I did not care for it, yet I have had some chance to judge of that matter, and one of the great troubles is that these experts get on the witness stand and do not for a moment admit that they are mere citizens the same as other witnesses, but want to claim privileges; here they make a great mistake; they are imprudent and indiscreet in their replies to counsel on one side or the other. Another thing is, they undertake to explain the lawyer's questions instead of making the lawyer explain the questions himself; undertake to answer two questions with one answer and they make a mistake; but in regard to

experts, the principle that applies to medical men, civil engineers and everything else is so broad that we can not interfere with it; that is that the judge is the one who determines as to the qualification and the capacity of a person to testify on a hypothetical state of facts; there is almost a general rule to this effect; and all questions that you are asked as an expert must be asked and answered on a hypothetical basis, not as a matter of fact. That runs all through the law; but if the doctors were a little more careful in giving a well protected answer instead of a broad and vulnerable one, stating that such a thing is utterly impossible and all that sort of thing, they would not get themselves in half as much trouble as they do.

The expert who gives the lawyers advice outside of the court room and who assists in the preparation of the case is all right, but sometimes he is decidedly offensive. You will see him crawling all over counsel on the other side, and he discounts his usefulness before the jury and before the court. He certainly is simply committing professional suicide. I think that if the legal position that the medical man occupies in the court is recognized as no different from that of any witness, if that were impressed upon the medical profession more fully, it would save the medical expert from a hundred indiscretions. All he has got to do when he sees that the lawyer is embarrassed for him on a certain point, is to switch off on another line. That will break the lawyer up.

DR. CLARK GAYEN—I notice that I have used unconsciously legal terms that are misunderstood by us as medical men, and I think an explanation of these terms will perhaps remove the necessity for some of the criticisms that have been offered. For instance, I used the term "witness as counsel." I do not mean by that that the witness shall not consult freely and advise freely with counsel in respect to the case; but when I say "witness as counsel," I mean counsel in the court room. The law does not understand anything else in speaking of counsel, except as counsel in the case in the court room. You will constantly see medical experts and medical men sitting by lawyers and advising them, and virtually acting as counsel. The lawyer is a mere parrot repeating the words the doctor has put into his mouth, and that is what I object to. There should be the freest consultation, and the freest advisory relation between the expert and lawyer before the case and during the case for that matter, but there is no better way for a lawyer to commit professional suicide than to have the medical expert sit by actually as counsel in the case.

In respect to the term, "opinion on the case," that is a legal phrase and has a very distinct meaning in the law. A lawyer would not hesitate on that a moment. An opinion is a very different thing from an "opinion on the case." Dr. Emerson has very well illustrated that. You can ask a medical man, stating the evidence that has been adduced, Do you think such symptoms as these indicate insanity? What is your opinion as to the mental condition of an individual who presents these symptoms, enumerating all the symptoms that have been presented; now you give your opinion with regard to that. There is no objection, whatever, to giving an opinion in that case. But when you say, Have you heard the evidence in this case, and what is your opinion as to whether the prisoner is sane or insane? That is just exactly what the court and jury are there for to determine, and every supreme court has reversed cases where questions like that have been asked instead of the proper hypothetical ones. It is a direct invasion of the province of the jury. It may be a little unusual to medical minds to make the discrimination, but there is from a legal point of view the widest discrimination between giving an opinion on that identical case and giving an expert opinion relative to the facts involved in that case.

Now with reference to the calling of experts, I would not do away with the English system at all, but I think that experts should be called something in this way: each side should hand in a list of experts that he wishes called and the court should select an equal number from that list after hearing evidence, if necessary, with regard to the qualifications of any of the men on the list. The court can, as it were, stop the proceedings and make a side issue of it as to whether this physician is expert with reference to the particular question, and the court should do so. I think the greatest trouble that arises is in bringing in men who know nothing about the particular subject involved and opposing them to men who are learned. Why the jury is very likely to conclude that the ignorant man knows the most, because the learned man makes discriminations which are absolutely incomprehensible to them. The test should always be experience, and that test is recognized by the law.

PUERPERAL HEMORRHAGE.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY JAS. P. KERR,
PITTSBURGH, PA.

The subject which I have the honor of bringing before you is one which demands as much consideration as any in the whole category of medicine or surgery, because it is one of the most frequent complications of labor, and if the means and remedies are not applied and administered speedily and effectually, death is sure to ensue.

It is most apt to come on at a time when least expected, and if not properly treated to be rapidly fatal. Practitioners in general are too apt to consider all cases of labor normal, and not make any preparations for this accident, which is likely to occur at any time; so it is our duty to impress upon them the necessity of careful preparation and of a thorough study of each individual case. Obtain, if possible, the patient's family history, discover whether she is, or is not, of a family of bleeders, and how much blood she has lost during her regular menstrual periods. If a multipara, ascertain whether she has had hemorrhage at her previous confinements; how many children she has borne, and the length of time between each conception. I am aware of the fact, gentlemen, that in a country so cosmopolitan as ours, the general practitioner (who is usually called upon to fight these battles single-handed in the dead hours of the night, when assistance is far away) occasionally does not have an opportunity to see his patient until summoned to her "lying-in" bedside, consequently we oftentimes know nothing of our cases until brought face to face with them.

There is no class of cases which require more prompt action, cool and wise judgment, than that of puerperal hemorrhage. The golden rule of surgery must be obeyed to the letter, that is—"do not let your patient bleed to death;" and to prevent that requires, first, a preparation for it; and second, a prompt application of the means and remedies which you have provided. Picture a case of puerperal hemorrhage. The obstetrician is called; finds the mother on her "lying-in-bed" suffering the effects of an effluence; her heart is buoyed up by hopes and expectations that her agonies will soon be over, and that she will soon press to her bosom a living issue.

Her woe!—such hopes and expectations can only

be experienced by a woman on the "lying-in-bed." Finally the child is delivered, the mother is happy and her friends are rejoicing; when suddenly without a sign of warning the life-giving fluid begins to flow away in torrents, we hear the death-like gurgle, we see the bleached and anxious expression and the purple lips; we feel the clammy and velvety condition of the skin which always supervenes a great loss of blood. Our patient is pulseless, very restless, pupils dilated, and to all appearances the "King of Terrors" is about to invade this home,—and instead of joy and pleasure, we will have tears and sorrowing. This woman, who has children dependent upon her, who are dear to her, and to whom she is dear, is cut down in the full vigor of womanhood without one moment's notice. The time to act is at hand; we have no time to call a consulting physician; we must act promptly to save the life of this mother and wife.

Then do you wonder that we insist so much upon a thorough knowledge of this subject, when a patient's life is thrown in the balance so suddenly, and nothing can save her except the prompt and skillful action of her attending physician who, to act, must have a thorough knowledge of the subject and be able to meet all emergencies? To be able to remove the cause and to apply the means and remedies which will put a new life in that prostrate form, and restore the wife to her husband, the mother to her children, and bring joy and happiness back to that household is characteristic of a true trustworthy physician.

The skillful and experienced obstetrician who considers the responsibility which devolves upon him, the implicit confidence placed in him by his patient and her friends, has in consideration all the complications which may befall her during her parturition; he also considers by what means he is to successfully combat these complications, should they arise, to save the life of his patient.

The necessity of strict asepsis is apparent to every one in the lying-in chamber. Always hope for a speedy termination with happy results, but be prepared for any emergency which may arise; who can tell when, after the delivery of the child, he may be compelled to introduce his hand into the uterus to control a fatal hemorrhage, and would it not be criminal, with our knowledge of asepsis, to carry septic material into that uterus, and endanger the life of our patient? It only requires a few minutes to render your hands, at least, practically aseptic.

We believe if there was more attention given to aseptic midwifery, the mortality would be much lower. This brings us to the consideration of a class of cases which we encounter occasionally during the walks of obstetric practice, which strike the heart of the accoucheur with alarm, because of the gravity of these cases in the hands of the most skillful obstetrician. I refer to accidental hemorrhage. This accident is caused by the premature detachment of a normally situated placenta, which may be either partial or complete. It may occur at any time during pregnancy, but rarely until the later months; often not until labor has commenced. When the blood makes its way between the decidua and the membranes appearing per vaginam, we then have a typical case of accidental hemorrhage, but the blood may be retained in the uterus, constituting internal or concealed hemorrhage. In concealed hemorrhage

the blood collects either in the cavity formed by the central detachment of the placenta or between the uterine wall and the membranes, or in the amniotic cavity, or free in the uterus, but retained by a completely obstructing presenting part. Accidental hemorrhage is comparatively rare, especially the grave form. The detachment of the placenta causing this complication is most frequently due to an injury, such as a blow on the abdomen, or a fall. Emotion or over-exertion may start a separation of the placenta. If that imperceptible uterine action that goes on just before labor sets in should be unusually violent it may cause a small vessel of the placenta to yield, and the effusion which would be the result would act as a foreign body and excite further uterine action, and a partial or complete separation of the placenta would be the legitimate result. It may also be the result of some of the general diseases, such as typhoid fever, variola and scarlet fever, or of some of the local diseases, such as albuminuria, acute yellow atrophy of the liver, also degeneration, and disease of the placenta itself. It is generally met with in women who have borne many children, and in rapid succession, and in those who are suffering from anemia or impaired health from any cause. It is rarely if ever met with in the primipara. I had the misfortune to see a woman die from this accident a few years ago. I have stood by the bedside of many poor individuals, in all conditions and circumstances of life, and watched the last spark of life expire, but I have never had an experience so sad as this one. If there is anything that will strike the responsive chord in the heart of man and set the strings of sympathy in tune, it is to stand by the bedside of a dying mother and see the human life ebbing away. Mrs. L., 37 years of age, the mother of six children, who was expecting to be confined at any time; a woman of good family history; she had not had any complications during her previous confinements; never had an abortion or miscarriage; a woman of fine physique, but whom I had never seen until summoned to her dying bedside. On the morning of the accident she arose at the usual time, and expressed herself as feeling as well as she had at any time during her pregnancy. I presume she had albuminuria, from the condition of her feet and limbs, and from the symptoms which I elicited from her husband. I was called about 11.30 A.M. She had not had any pain; had not received an injury; the uterus was not greatly distended. The accident was apparently without any cause except the possible albuminuria, and came on without any warning. There was a sudden gush of blood which rendered the woman pulseless; in fact when I arrived she was completely collapsed and still bleeding. I immediately lowered the head of the bed, injected ergot, brandy and ammonia hypodermically. I tried to excite uterine contractions by external manipulations of the uterus which was soft and flabby. Made an examination, found the os dilated, soft and patulous, so I delivered by podalic version, which was accomplished without any difficulty; carried ice into the uterus, vinegar, turpentine and hot water; continued my external manipulations but could not stimulate permanent contractions and retractions of the uterus. Hemorrhage went on, and the woman died in about fifteen minutes after delivery. The placenta came away with the child, and from the coagula which had formed

upon it I should think it had been wholly detached. Hemorrhage was so severe in this case from the beginning, that death was unavoidable. It was just about an hour from the time hemorrhage began until the woman was a corpse.

Open hemorrhage is recognized without any difficulty, as the appearance of the blood is sufficient and makes the diagnosis. Concealed hemorrhage is more difficult to diagnose. The symptoms are obscure. Pain is usually present, and severe in character. Associated with it are the symptoms of acute anemia, and in severe cases even collapse, without any apparent cause. The uterus is usually greatly distended. Labor pains diminish or cease entirely. This accident may be confounded with rupture of the uterus. In rupture the uterus is smaller, and the fratus may be felt in the abdominal cavity through the thin belly wall. The presenting part recedes, if it is not wedged in the pelvis. The rent may also be felt and sometimes prolapsed intestines.

Placenta previa is one of the causes of hemorrhage, but as it is a subject itself it would require too much time to discuss it in this paper. Hemorrhage during or after the third stage of labor may be either primary or secondary. If it occurs during or within twenty-four hours after the third stage of labor it is primary. If at any time during the puerperal period thereafter, secondary. It may come on immediately after the birth of the child, and before the expulsion of the placenta, or it may follow the delivery of the placenta. Any circumstance, whether functional inactivity, organic defect, emotional disturbance or mechanical obstruction to a firm closure of the uterus, acts as a cause and invites hemorrhage. The anatomical relation of the muscular fiber of the uterus to its vascular system is such that during tonic contractions and retractions of the uterus, the muscular fiber acts as a ligature to the arteries and sinuses which ramify its walls, and hemorrhage is impossible. It is very important, in fact absolutely necessary, to be familiar with the cause or causes of this accident, because intelligent and skillful treatment is based upon the cause, and a successful termination of the case will depend upon one's ability to early recognize the cause and remove it. Functional inactivity or uterine inertia, bears a casual relation to this complication. The predisposing causes of uterine inertia are, hydramnios, twin pregnancies, constitutional weakness produced by some of the wasting diseases, insufficient food or bad hygienic environments, exhaustion from prolonged labor—any cause that so affects the constituents of the blood as to prevent the formation of thrombi, predisposes to hemorrhage; also, hemorrhagic diathesis, rapid delivery and the employment of anaesthetics during parturition. Hemorrhage during and after the third stage of labor is often caused by the retention within the uterus of the placenta, or parts of the placenta. I do not think any obstetrician of to-day, skilled in the practice of his profession, with the gift from God of good common sense, would dare to leave the placenta as a whole in the uterus, although this practice at one time had its advocates; but it is not rare for parts of the placenta to be retained.

The formation and retention of blood clots may also cause hemorrhage. This is generally due to uterine relaxation, uterine displacements or the retention of some small pieces of the placenta around which the clot formed, which may be either the

result of too forcible or premature efforts at expression or extraction; or abnormal placental adhesions, or some abnormality of the placenta, multiloba succenturia, etc.; lacerations of the cervix uteri, which may extend so far as to sever the circular artery. Lacerations of the vagina, or of the perineum, or extreme soft parts, are sometimes the source of serious hemorrhage after firm contractions and retractions of the uterus, and a careful examination will reveal the true cause of the hemorrhage. These lacerations should be repaired at once, so it is necessary for an obstetrician to be a surgeon as well. Many previously healthy women are made invalids by not receiving proper attention from the attending physician.

Repair these lacerations immediately, and prevent the suffering which often accompanies them. Fibroid tumors sometimes cause hemorrhage by preventing firm contractions and retractions of the uterus. Varicose veins in and about the vulva are sometimes the source of hemorrhage. Carcinoma, either of the body of the uterus or cervix, may cause hemorrhage. Retarded involution, which is often due to some of the displacements, such as retroflexion, is the most frequent cause of secondary hemorrhage, although all the conditions which cause primary hemorrhage also cause secondary hemorrhage. We are glad to say that severe postpartum hemorrhage is generally a preventable accident by a skillful management of the third stage of labor. If every case were treated as a case of itself, and as though hemorrhage was impending, there would be very few accidents of this kind. The attention should be directed to securing tonic contractions and retractions of the uterus as a prophylactic. This is done by carefully following the uterus down with the hand when the child is expelled, also by making pressure over the fundus, and by external manipulations. If the uterus is soft and flabby, give some of the preparations of ergot, *prof. ergotin*, by hypodermic injection. Misraichi claims that caffeine acts more readily than ergotin, especially if the patient has lost much blood.

If the patients are known to be bleeders, or to have had hemorrhage during previous confinements, they should be prepared for their parturition several weeks before it is expected to come on.

Dr. John M. Duff of Pittsburgh, is in the habit of giving such patients strychnia. He begins six weeks or two months before the expected time; administering $\frac{1}{16}$ to $\frac{1}{32}$ grains of the sulphate three times a day. Considering the physiological action of strychnia, we think this treatment rational and scientific. Bossi considers *hydrastis canadensis* a very useful remedy in the treatment of hemorrhage both during pregnancy and during and after parturition. He administers it to patients with a predisposition to flooding, and claims excellent results. In the treatment of accidental hemorrhage, we must strive to control the hemorrhage and also sustain the patient. If the os is dilated, it is good practice to deliver as soon as possible; if it is not, use the Barnes' dilators and proceed to deliver. Murray advocates plugging the vagina where the os is undilated. I do not think this good practice, because it will not prevent the hemorrhage, but will only prevent its escape from the vagina, and the woman may literally bleed to death in her own womb. When the uterus is empty, we have more control over it; it may then be packed

with iodoform gauze, as recommended by Dührssen. Hot water injected into the uterus acts very kindly sometimes. Ice introduced into the uterus, and turpentine or vinegar, often give very satisfactory results. If these fail we may resort to the application of styptics. Ergot should be administered either hypodermically or by the mouth. The patient must be sustained, so we resort to stimulants. Brandy, ammonia, ether, etc., should be administered hypodermically and by the mouth. Warmth should be applied. The patient's head should be lowered and if necessary the extremities may be bandaged from the distal end up. A successful termination of the case will depend on our ability to control the hemorrhage, and the recuperative powers of the woman. This treatment also applies to severe postpartum hemorrhage. If the hemorrhage after labor is due to retention within the organ of portions of the placenta or clots of blood, they should be removed at once.

Dierska's method of controlling postpartum hemorrhage is to press the fundus firmly with one hand, with the other remove all clots, and then introduce into the uterus and upper part of the vagina two or three small pieces of ice. The ice is left in place for a few minutes, and pressure kept up for a quarter of an hour longer. He believes this method to be extremely efficacious.

Kochs recommends a mode of treatment of postpartum hemorrhage, which is at least novel; that is to invert the uterus, and put an india rubber band around the neck of the inverted organ; after six hours the band is removed and the uterus replaced. If hemorrhage is due to a laceration of the cervix which severs the circular artery, the artery should be ligated and the laceration repaired; lacerations of the vagina, perineum and soft parts should be repaired if possible. Fibroid tumors, if they assume the shape of an intra-uterine polypus, should be removed by scissors, after ligation of their base. If they can not be removed, administer ergot, quinia, and apply the faradic current daily. When hemorrhage is due to carcinoma, plugging the vagina is good treatment. If the patient is suffering greatly from anemia, we can resort to transfusion of blood, or, which is just as beneficial, a 3 per cent. solution of common salt.

Dr. T. RIDGEWAY BARKER of Philadelphia, took exception to the plan of treatment suggested for the control of puerperal hemorrhage. He was a firm believer in the methods mentioned a few years ago, until he had a severe case of postpartum hemorrhage which terminated in the death of the patient. He had learned from experience in this case that ice, hot water and ergot were entirely inefficient, and their use led to a waste of precious time. He recommends a tampon of antiseptic gauze. In slight hemorrhage the measures first mentioned would effect control. He thought the number of cases seen by the practitioner were in inverse ratio to his experience in midwifery.

Dr. E. P. Davis of Philadelphia, said if the uterus is held in one hand and tamponed with the other it is a physical impossibility for serious hemorrhage to occur. This is a comparatively modern procedure. In England they were again discussing compression of the abdominal aorta.

Dr. MORRIS of Wisconsin, had saved a case twenty years ago by compressing the abdominal aorta with the hand in the uterus, reinforced part of the time by the other hand pressing upon the uterus from without. Other cases were seen by him, and treated successfully in the same manner.

DR. WILLIAM L. BUECHNER of Youngstown, Ohio, finds that he is able to control cases of postpartum hemorrhage with hot water. Formerly he resorted to cold water and ergot with unsatisfactory results. Ergot judiciously administered in the second stage of labor controls hemorrhage, and he finds if he does not give it that clots form, and that later these clots give way and hemorrhage takes place.

DR. E. E. MONTGOMERY of Philadelphia, emphasized the advantage of using strychnia, not only prior to the delivery of women who are disposed to bleed, but subsequent to it with a view to arresting hemorrhage, to awaken the nerve centers and prevent the collapse that takes place by the loss of blood. He said we have no drug at the present day so effective in its influence upon the heart's action and muscular coats of the vessels as that of strychnia. He doubts the practical value of compression of the abdominal aorta, especially with the hand in the uterus, as part of the blood supply comes from the ovarian arteries, which arise high on the aorta.

DR. GILES S. MITCHELL of Cincinnati, Ohio, laid stress upon the importance of prophylaxis of postpartum hemorrhage. He believes that almost every case of postpartum hemorrhage can be prevented if the accoucheur pays proper attention to the third stage of labor. He has had a tolerably large obstetric practice, and does not remember of ever seeing a case of postpartum hemorrhage. He has seen one case of accidental hemorrhage from the premature detachment of the normally implanted placenta. Fortunately the patient recovered.

THE ROUTINE PRACTICE OF ADMINISTERING ERGOT AFTER THE THIRD STAGE OF LABOR.

Read before the Section of Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY T. RIDGWAY BARKER, M.D.
PHILADELPHIA, PA.

While the routine administration of any drug, one must admit, can scarcely be considered an indication of the highest degree of scientific knowledge yet, as the practice of medicine is not, and never can become, an exact science, since the personal equation always contains an unknown quantity, *vital assistance*, I think we may, without violation of current practice, adopt with advantage such a procedure.

The old and apt proverb that an ounce of prevention is worth a pound of cure applies so forcibly to the employment of ergot after the termination of labor, in order to secure firm uterine muscular contractions and render them tonic, that this course would seem to be not only justifiable but actually indicated.

Were it possible to prognosticate with any measure of certainty that Mrs. A. will suffer from uterine inertia with resultant hemorrhage, while Mrs. B. will not, then the opponents of this method would have some grounds on which to base their antagonism; but unfortunately for them, this foretelling the course of events has no foundation in fact and rests largely upon assumption, often not even reinforced by experience.

I think I may declare, without fear of contradiction, that the occurrence of postpartum hemorrhage is due principally to a lack of correlation between uterine muscular contraction and coagulability of the blood; and while the latter, as I pointed out in a pa-

per read before the Philadelphia Obstetrical Society in February, 1893, can readily be ascertained by noticing the tendency to clot formation by the blood escaping from the birth canal during the early stages of parturition, the other factor, (muscular contraction), must remain in doubt, since uterine exhaustion is liable to occur when least expected. The realization of the above facts is absolutely necessary in order that one may follow out the arguments and results offered for consideration.

Those who take exception to the routine practice of administering ergot, do not hesitate to say that it is suitable in most, if not all, cases of threatened postpartum hemorrhage, or where the uterus fails to contract promptly after the completion of the third stage of labor.

This is undoubtedly sound reasoning, so far as it goes, but those on the affirmative side of the question say that it is not far enough.

As I have endeavored to show, one can not tell when uterine inertia will occur; it may be within five minutes of the delivery of the fetus or it may be five hours. Therefore, under such circumstances it is necessary in order to avoid this dangerous complication, that one resort to precautionary measures in every case. 'Tis true, every woman who is confined, if properly attended does not suffer from postpartum hemorrhage, nor does the woman who is so afflicted necessarily die from its effects, yet it is too great a risk to run when nothing is to be gained thereby but rather a loss sustained, as I shall strive to prove.

It has been said by some, who have given this method of administration a trial, that it "is neither necessary, expedient or devoid of danger." Further objection is offered that its routine use is liable to increase the parturient's discomfort by subjecting her to more severe and frequently recurring after pains.

This is, in a measure, in accord with my observations, but I look upon after pains as synonymous with uterine contractions and while for the first few hours the discomfort, as alluded to, is somewhat increased, I hold that this is more than balanced by the advantages which accrue from the immediate expulsion of all clots and debris from the uterine cavity, the more perfect and permanent closure of the uterine sinuses and the reduction in size of the placental site. It is further claimed that there is danger in its administration from the fact that it may convert a simple hemorrhage into a concealed one and thereby increase the risk of sepsis. Now just how it is possible for ergot to be guilty of such a thing I fail to comprehend.

If the statement is based on the assumption that the drug is capable of causing complete stenosis of the cervical canal, I would ask for proof of a single case where such a condition could be so ascribed.

In the first place, the effect of ergot is expended upon the whole layer of circular muscular fibers of the uterus, and not solely upon those in the immediate vicinity of the cervix.

Besides the stimulating influence is not limited even to this layer but causes the longitudinal fibers, though to a less degree, to contract also. Some have asserted that they noticed a rise in temperature follow the routine employment of this medicine.

Such, however, has not been my experience; on the contrary, I have found the reverse to be the case, which I credit, not to any antipyretic effect inherent in the

medicament, but to the more perfect retraction and depletion of the uterine vessels.

That there exists great diversity of susceptibility to the action of ergot none will deny, but the variability would appear to be due in no slight degree to the strength of the preparation, and the time and method of administration.

The above are some of the more general objections offered in evidence against this practice and yet, I can not but think they are more imaginary than real, since the routine method is being so generally adopted by some of the greatest clinicians and teachers in this country and Europe.

Bussey of Washington, D. C., writing on the conduct of labor in "Hirst's System of Obstetrics," says: "The routine administration of ergot at this stage of labor (after delivery of the placenta) is approved and practiced by many, if not a majority, of the most experienced and successful obstetricians, because it secures firm and persistent contraction of the uterus, lessens the danger of postpartum hemorrhage, protects in some measure the patient from septic complications, and promotes involution, whilst the dangers, if any, of producing hour-glass contraction of the uterus are too remote for consideration."

I therefore feel emboldened, when supported by such an authority and the results of my own personal experience, to declare myself in favor of this routine method, since by such means hemorrhage and its accompanying dangers are wellnigh impossible. By the employment of ergot, in suitable doses, we place a trusty servant on guard to watch the uterus and see that it performs its duty, and should it be unequal to the task imposed upon it then this agent is at hand ready to lend assistance.

Through its activity the uterus is reduced in size thereby lessening its encroachment upon the contents of the true and false pelvis. Moreover, we can not fail to realize that by the closer crowding together and more perfect rearrangement of the muscular fibers the sinuses are practically obliterated, the thrombi smaller and the congestion of the organ relieved.

Were the beneficial effects of ergot limited to the reduction in size of the placental site alone, it might well be considered a boon, for of all points within the cavity of the uterus this is the most vulnerable for the entrance of septic material since it is devoid of a protecting layer of epithelium.

In this respect differing from the other portions of the cavity which recent researches go to prove is lined by an embryonic layer of epithelium which, while not attaining its full development until some weeks after separation of the decidua, yet serves a useful purpose as a protective against the entrance of pathogenic organisms.

Accepting and appreciating this fact, one can not fail to realize the importance of reducing this denuded area to the minimum. Though, as has been stated, the immediate discomfort of the parturient may be somewhat increased for a few hours, yet the subsequent annoyance from after pains is avoided, since the uterine cavity on the completion of labor is freed of all clots and debris which by their presence tend to excite muscular contractions.

As to the danger attending the routine administration of ergot, I can not but think it is largely visionary, at least I have yet to meet with a single case, though practicing this method for over two years, in

which, in appropriate doses it has been productive of baneful effects, nor so far as I know, has any proof to the contrary been presented.

Some of my opponents may claim that it is bad practice to interfere with nature when she is doing her work properly, and at first it would seem so, but when we consider that it is not *interference* but *assistance* that we render, the whole aspect of the case changes, and what appeared to be meddlesome midwifery proves really to be a judicious application of a scientific agent in the furtherance of a physiological process.

The method of administration has, I believe, more to do with the rate of absorption and the degree of activity than is generally supposed. Though at first I prescribed ergot in the form of fluid extract by the mouth in half drachm to drachm doses, I have of late discarded it, preferring one-quarter of a grain tablet triturates of ergotin, since their ingestion is free from the bad taste and stomachic irritation which always accompanies the fluid preparations.

With regard to the hypodermic administration of ergot, I would say, that I have employed it in a considerable number of cases and found it to act promptly and efficiently, yet as the needle gives pain and its use is often objected to by the patient, without offering any additional benefit, I now but rarely have occasion to resort to the subcutaneous method.

Where one has, however, to deal with a patient in a state of extreme exhaustion or collapse associated with or due to hemorrhage, this agent can not be relied upon since for its activity is required a more or less responsive nervous system. This fact must be borne in mind, lest one postpone other and more efficient artificial measures for the control of hemorrhage until too late, when the rescue of the parturient becomes impossible.

As to the oft discussed and disputed point that ergot assists and hastens involution, I wish to place myself on the affirmative side, believing as I must from clinical experience that it does facilitate fatty degeneration of the uterine muscular fibrillæ through its indirect influence upon the uterine blood vessels.

It has been stated by my opponents that in the routine practice of administering ergot one can not know how large a dose to prescribe; my rule has been to order one-quarter grain of ergotin in tablet triturate form, to be taken immediately after delivery of the placenta, and this dose to be doubled and repeated every half hour for the control of any excessive bleeding.

In this way, I believe I have avoided the ingestion of any amount of the drug in excess of actual requirements. The dose I am in the habit of employing may be said to be very minute, but I care not for its minuteness if it only does what is demanded of it.

The object desired is not to drive nature to her work but to assist her should she fail. One may very properly ask, how do you know that a dose of the size mentioned does benefit the parturient or even stimulate uterine contractions? To which I would reply, from the fact that shortly after its administration, uterine contractions are more frequent, lasting and complete, and by the prompt expulsion of all debris.

In recommending the routine employment of this cathartic it is not to be supposed that other measures are to be overlooked or neglected for the prevention of postpartum hemorrhage; just as much

care should be exercised during every stage of labor as under other circumstances. The administration of ergot is not intended to correct and and injudicious midwifery practice, but to aid and facilitate in the perfect restoration of the parturient to a physiological non-pregnant condition.

To summarize, then, the advantages derived from the routine employment of ergot after labor, one I think, is justified in stating that, first, it insures the woman against possible uterine relaxation; second, it causes a reduction in the size of the uterus, which consequently encroaches less upon the pelvic viscera; third, the vessels in the uterine muscular walls are depleted and the force of the blood current reduced; fourth, it secures permanent closure of the uterine sinuses and allows the formation of firm clots at the mouths of the lacerated vessels; fifth, it reduces the area of the denuded placental site thereby lessening the danger of the entrance of septic matter into the circulation; sixth, it markedly diminishes the size of the uterine cavity with the resultant expulsion of all debris; seventh, it shortens the duration of after pains and renders the occurrence of fermentative changes within the cavity impossible; eighth, it hastens and facilitates the physiological processes incident to involution; ninth, the tablet triturate form of administration is to be preferred since it is rarely attended with nausea or vomiting; tenth, that it never does any harm in suitable doses and is always productive of good.

Quite the contrary, I believe to be the case, and have so placed myself on record, when ergot is prescribed during any of the three stages of labor. It is then a dangerous remedy and one likely to do far greater injury than any fancied good.

For the above valid reasons I have adopted the routine practice of administering ergot after the third stage of labor and would recommend the same to those engaged in obstetric work as a valuable conservative measure.

DR. JOSEPH EASTMAN of Indianapolis, Ind., said we must not forget that it is the law of all organs in the human body to have a period of life and a period of rest. He objects to the routine use of ergot, because it substitutes tonic (unnatural for clonic (natural) uterine contractions. He is confident that he has seen cases of subinvolution of the uterus produced by the too persistent use of ergot. He has seen cases where strychnia replaced ergot without interference with the normal clonic contractions of the uterus. He has on previous occasions said, when speaking of the prevention of subinvolution of the uterus, that the use of ergot should be restricted to the third stage of labor. He has gone even further and said that its use should be restricted to the satchel and not used at all, but this he thought was too extreme.

DR. J. A. MURPHY of Wilkesbarre, Pa., finds that in cases where ergot fails to secure uterine contraction, mistletoe acts well.

DR. JOHN M. DUFF (the chairman) of Pittsburg, Pa., said he read a paper on the same subject last year in which he took an opposite view and argued against the routine use of ergot. He thinks the routine practice of administering ergot after the third stage of labor is unscientific. He administers it where he thinks it is indicated, and the obstetrician who is scientific and careful in his work will nearly always be able to tell in what cases it is indicated. Those who have not tried strychnia in connection with cases in which they are afraid of hemorrhage, or in which there are severe after pains, will be agreeably surprised with the bene-

ficial effects of strychnia. (See *Am. Jour. Obstet.*, 1892, p. 100.)

DR. C. S. BAYNE of Chicago, Ill., said he had observed the practice of administering ergot. In several patients who were nursed children he finds that its use has a perceptible effect in drying of the milk secretion, and his attention was called to the possible effect of it in the same way given immediately after labor. An other objection was the uncertainty of its preparation.

DR. BAUKER, Indianapolis, said he had no doubt that if ergot were administered immediately after labor in the manner spoken of, large doses, it would give rise to the conditions named.

THE ABUSE OF EMMET'S OPERATION FOR LACERATION OF THE CERVIX.

Read at the Session on Obstetrics and Diseases of Women at the Forty-fourth Annual Meeting of the American Medical Association.

BY E. C. PUBLEY, M.D.

CHICAGO.

Emmet first operated for laceration of the cervix uteri in 1862. His published statement on the operation appeared in 1869. He published an elaborate paper on the subject in 1874, and another in 1877.¹ These papers were the outcome of many years' practical observation, not only of the operation itself, but of its relation to numerous pathological conditions, some of which the operation might cure, and others of which the abuse of the operation might cause.

The original literature was characterized by conservatism, by completeness, by deliberation; it warranted, and subsequent results have justified, the prophecy of Marion Sims, who said: "We can't modify the operation; we can't change it; we can't improve, for it is perfect; perfect in its method, and perfect in its results. Like all new operations it is likely to be abused, but the time will soon come when it will assume its place in the foremost rank of useful improvements." Notwithstanding the clearness with which the indications and contra indications, and the technique were defined, the operation, although no longer new, is often so badly executed as to be followed by most disappointing and sometimes by injurious results.

We pass by with simple mention the abuse of the operation in cases unsuited to it, including those in which the laceration is slight, and not associated with uterine catarrh, cervical cystic degeneration, cervical erosion, cervical eversion. We also exclude a large class of unfortunate cases, in which trachelorrhaphy is too often performed regardless of other and more important lesions, especially lesion of the uterine appendages and other peri-uterine structures.

The present discussion is confined to those failures following trachelorrhaphy, which are consequent upon faults connected with the execution of the operation itself; faults which often necessitate even the splitting apart of the united flaps, and doing the operation over again.

The most common faults in the execution of trachelorrhaphy may be indicated as follows: The operation may fail or do harm.

1. Because the operator has disregarded the presence of endometritis.
2. Because the os externum has been closed so

¹ *American Journal of Obstetrics*, Nov., 1874.

² *American Practitioner*, January, 1877.

tightly as to obstruct the free outflow of uterine secretions and menstrual fluid.

3. Because the cicatricial plugs in the angles of the laceration have not been removed.

4. Because diseased cervical glands have been rolled into the cervical canal where they find expression either in the form of cervical catarrh, or of retention cysts.

Endometritis, which complicates so many cervical lacerations may pertain specially to the vascular structures or to the glandular elements of the uterine mucosa, and may consequently give rise to menstrual disorders or to uterine catarrh or to both. Among menstrual disorders menorrhagia is most common. Granular endometritis furnishes a positive indication for forcible dilatation, curettement, irrigation, and the application of strong carbolic acid and iodine, all of which should immediately precede closure of the cervix, except in aggravated cases when the curettement should be followed by thorough and repeated uterine tamponade of gauze after the method popularized by Dr. Polk. This tamponade would postpone the suturing until after the cure of the endometritis. Undoubtedly all this may be successfully done after the trachelorrhaphy, and in exceptional cases such a course might be wise, but it would reverse the more natural order of things.

First, cure the catarrh, then close the cervix to clinch the cure. But why close the cervix at all, if the catarrh is cured? It is a principle in physiology that if irritation be applied to the outlet of a duct leading from a glandular system, the secretion of the glands will thereby become exaggerated and may become pathological, hence the closure of the cervix is now indicated, because it removes such a source of irritation. Since following this line of practice my results have so much improved that I now hesitate to close the cervix without at least an exploratory curettement which often brings away a surprising amount either of granulation or of other material having a similar appearance, whose presence had not been suspected.

The evil consequences of closing the os externum to such an extent as to obstruct the free drainage of uterine secretions and menstrual fluid, are familiar to all observers. The pathological anatomy observed after such operation is the natural outcome of the stenosis which is often so extreme as to exclude the finest probe, and sometime amounts to total atresia. The secretions accumulate, distend the uterus, and sometimes even the Fallopian tubes; the secretions become decomposed, induce endometritis, metritis, salpingitis. These inflammations may even extend still further with most disastrous results, or may only keep up such a chronic irritation and congestion in the pelvis, as often to reduce the victim to a state of helpless invalidism. The rapid and complete relief which often follows the restoration of the normal caliber of the cervical canal and os externum, proves that the uterine canal is a natural drainage tube, the integrity of which is essential to health. In such cases, however, dilatation, curettement and uterine tamponade, or some other method may be further indicated, to overcome the endometritis, as induced by the long retention of irritating secretions. The simple enlargement of the os externum, however, by incision is not permanent in its effect, because the structures involved are cicatricial,

and therefore prone to recontract. A plastic operation, by which mucous membrane is made to cover the cut surfaces is imperative. Schroeder's operation fulfills the indication perfectly.

We may omit any extended consideration of Emmet's injunction for the removal of all cicatricial tissue from the angles of the wound, although this important step in the operation is often disregarded. However, failure to remove it commonly results in failure of union, or imperfect union; a fortunate compromise for the patient, since the cicatrix is much less injurious with the laceration open, than with the laceration closed. When, unfortunately, union has taken place, the train of nervous symptoms which follows often necessitates the removal of the cicatricial plugs and the reclosure of the wound.

The common forms of disease of the cervical glands, i. e., the nabothian glands of which Tyler Smith estimates the number to be 10,000 in the virgin cervix, often demand special attention, in connection with the closure of the laceration. One form is characterized by the excessive outpouring of the familiar gelatinous white-of-egg-like secretion which acts as a tenacious plug in the cervical canal, very difficult to dislodge and usually present in enormous quantities in the upper portion of the vagina.

When the cervix has been closed, after the classical method of Emmet, this secretion is apt to continue unabated, nor is the usual preparatory treatment of topical applications effective for the removal of the disease. Indeed, any treatment in this form of disease which does not include the removal of the offending glands themselves, usually fails. Three methods of destroying the diseased glands are practiced:

1. Strong cauterization.
2. The free use of the sharp curette.
3. Excision.

The first two methods, i. e., cauterization and sharp curettement, are objectionable for the following reasons: First, the glands are so deeply seated in the mucosa that they always escape the caustic and the curette, unless these have been used with such hardihood as to produce excessive cicatrization and consequent stenosis, a condition quite difficult to remedy, even by plastic surgery. The excision of the glands on the other hand, and the closure of the cervix by the method of Schroeder, removes the disease and leaves the organs in a physiological state. After this operation, the cut surfaces can not cicatrize and contract, because covered by mucous membrane, this having been united by means of sutures to the intra-cervical mucous membrane. Schroeder has also found this operation the only effective means of curing cervical catarrh, not only in cases of cervical laceration, but also in cases in which there has been no laceration. In the latter class of cases he makes bi-lateral incisions, and proceeds with the operation the same as in cases of laceration.

The other form of glandular disease of the cervix, is that known as cystic degeneration. The ducts of the nabothian follicles having become obliterated by adhesive inflammation, the follicles become distended by their own secretions, and form retention cysts. The great increase in the size of the lacerated cervix, both before and after trachelorrhaphy,

phy is often due to the presence of cystic degeneration of these follicles; a pathological condition which often becomes much exaggerated when any of these diseased glands have been rolled into the cervical canal by trachelorrhaphy. Oftentimes the cysts are present in great numbers, and of such enormous size as to lead to the suspicion that the consequent enlargement of the cervix may be from malignant disease. Such a case has recently come under my observation, the patient having suffered from pronounced catalepsy since trachelorrhaphy was performed ten years ago. An examination showed atresia at the os externum, excessive enlargement of the cervix, right ovary partly fixed, size of English walnut, left ovary fixed, slightly enlarged. In order to ascertain the true condition of the interior of the cervix deep bi-lateral incisions were made, and the anterior and posterior lips were spread wide apart as they are in the most extensive laceration. Much pent up secretion escaped from the uterine cavity, showing that the tight closure of the os externum had converted that cavity into a retention cyst; large numbers of cysts of the nabothian follicles appeared in the cervix, some milary, others as large as small marbles. In the excision of these cysts, almost all the mucous membrane of the cervix was removed. The margin of the mucous membrane of the vaginal portion was then stitched with catgut sutures to the margin of the intra-cervical mucous membrane, both anteriorly and posteriorly, so as to fold the anterior and posterior lips of the cervix upon themselves. The lateral incisions were then closed with silk-worm gut sutures, leaving the cervical canal permanently patent. This operation was practically that of Schroeder. The perineum which was lightly lacerated was also closed. The operation was performed about six months ago, and the patient although naturally neurotic, reports herself free from cataleptiform seizures, since her recovery from the operation. This case, although striking, is only one of a large and increasing number of parallel cases, which illustrate possible evil results of bad surgery.

In the preparatory treatment for trachelorrhaphy, experience has shown that the simple puncturing of cysts of the nabothian follicles by means of the spear pointed lance is inadequate, because the cysts are prone to be refilled. They should either be destroyed by the cautery or excised. The excision may be of the individual cysts, provided they are not too numerous, otherwise of the cervical mucosa.

The evil results consequent upon the abuse of Emmet's operation, are frequently encountered, and a large part of the most necessary work, in connection with this operation, at the present time, consists of the conservative surgical procedures already outlined, the object of which is to undo work which has already been done. If the abuse of the operation has done much harm, the misguided practitioner must bear the burden of his own fault; the operation must not be made to do so for him.

ORIGIN AND DEVELOPMENT OF THE GENITO-URINARY ORGANS IN WOMEN.

Read in the Section on Obstetrics and Diseases of Women at the Forty-fourth Annual Meeting of the American Medical Association.

BY F. BYRON ROBINSON, B.S., M.D.

PROFESSOR OF GYNECOLOGY IN THE GEORGE WASHINGTON MEDICAL SCHOOL, AND HONORARY CLINICAL GYNECOLOGIST IN WOMAN'S HOSPITAL, 1015 FIRST GRAND AVENUE, S.W., DISTRICT OF COLUMBIA, D.C.

The following remarks are based on original investigation in the human and in the lower animals, especially the pig. The research embraces the examination of about 1,000 specimens of the genitals of the human and lower animals in various conditions and stages of development. The investigation was carried to the bird family, and some interesting information was gained. The development of the genito-urinary organs is one of the most fascinating of all studies, as the plans of evolution are most perfectly manifested in rapid succession. As the organs develop, the subjects of hypertrophy and atrophy are seen in their most typical forms. It is plain that in the embryo whole ages of evolutionary development take place in a few weeks, and that each of the distinct stages of the then distinct kidneys of mammals represent so many wide periods of animal life. The economy and conservatism of nature is shown in its most beautiful manner—in the development of the genito-urinary organs by inducing organs and ducts to act first for kidneys and excretory organs, and finally for egg channels and gestation sacs. The great capacity that organs have to modify themselves is a most instructive subject. Every young physician should acquaint himself with the embryological development of the part of anatomy to which his future practice is likely to lead. Embryology aids in comprehending the history of the growth of the genitals. It enables one to comprehend the adult genital organs and gives frequently a clue to their pathology. The so-called practical man may attempt to announce that the study of the development of the genitals is worthless because we can not change the course of deficient nature. But to the scientific physician every stage of the development of the genito-urinary organs is an incentive for hopeful acquisitions that may avert deformities. Malformation of the female genitals is simply nature caught in the act of wrong development. In the widespread awakening of the present it is interesting to observe the family physician attempting to study the female genitals so that he may understand arrest of development, relics of atrophied organs and tumors from the same. To be practical one must follow every stage of developmental structure. Comparative anatomy sheds a flood of light on such work, and if one will carefully investigate the growth of the Wolffian body among the lower animals and man, the adult form of the genito-urinary organs will be relatively easy of comprehension. About 1750, Dr. Wolff of Berlin, Germany, began to announce the results of his studies on the genito-urinary bodies. The subject was so attractive that it drew to it some of the most brilliant names of literature who have enriched our libraries. Mueller, Gartner, Rosenmüller, Waldeyer, Lankester, Raztke and Gegenbaur are but a few who have recorded their views on the Wolffian body. The magnificent labors of Halfour, which read like a bewitching story, aided by the industrious Semper, have enabled us to distinguish the three grand divisions of the Wolffian

LUNAR CAUSTIC.—"You are worth a great deal more to people at some times than you are at others," said the comet sardonically to the moon. "That's why they call you the silver moon."

"Yes," replied the luminary, sadly; "it all comes of having to be taken at my phase value."—*Washington Star.*

body. The best and most practical method of obtaining clear knowledge of the Wolffian body is to secure fetal pigs at the slaughter house. The development of the Wolffian body is similar in all mammals, and pigs can be obtained from a day old up to birth.

The Wolffian body is a complex, varying organ extending from diaphragm to cloaca or rectum on each side of the backbone. It is oval or spindle-shaped. In a small fetus the Wolffian body is the longest visceral organ and almost fills the abdominal cavity. The dominating fetal viscus is the liver, which rapidly enlarges and induces the large and prominent abdomen of early vertebral life so characteristic of infants. As the liver enlarges the Wolffian bodies decrease, perhaps in accord with the view that only one viscus can induce a high blood supply. Under a good lens one can easily see the longitudinal ducts of the Wolffian body, and also the very numerous short ducts that enter at right angles to the longitudinal ones. In typical specimens the naked eye detects all this and much more. I will note the study of the Wolffian body in three stages, as it occurs in nature:

1. The first stage includes the head kidney and its duct or ureter. It is called the first kidney or pronephros, and its duct is the Müllerian duct.

2. The second stage is known as the middle kidney and its duct. It is called mesonephros, and its duct is known as the Wolffian duct.

3. The third stage is called the third kidney with its duct. It is the kidney of adult life and its duct is the ureter of adult life.

1. The head kidney or pronephros will not be given much attention, as it is not functionally in the higher vertebrates. It may only be active in the fetal life of man for a few hours. But in lower animals, as fishes, it functions a whole fetal and adult life. It is the duct of the pronephros which concerns us as gynecologists, for it finally forms the vagina, uterus and Fallopian tube. The duct of the head kidney is known as Müller's duct. It is the Fallopian tube. It first carried urine from the head kidney, but it finally carried eggs. Nature is so conservative that she makes one organ do several functions. In the female, then, the duct of the first kidney carried urine and then eggs, while in the male it first carried urine and finally atrophies to a small cyst found on the testicle and known as the hydatid of Morgagni. Müller's duct of each side comes together in its posterior or lower two-thirds, and the approximated walls fuse so that one tube results. The fusion of the two ducts begins about the center of the middle third and proceeds both forward and backward. This peculiar method of fusion explains why we may have a single uterus and a double vagina, or a single vagina and a double uterus. The manner of fusion explains why we may have no uterus and a double or single vagina, or a uterus and no vagina.

The upper third of the Müllerian duct develops into the Fallopian tube. At the upper or anterior end of Müller's duct we can find, in some 15 to 20 per cent. of cases, a small pedunculated cyst known as the hydatid of Morgagni. This hydatid of Morgagni is perhaps the drawn out end of the upper mouth of the duct of Müller, or it may be a dilated uriniferous tubule of the pronephros. In the chicken the duct of Müller forms a single channel from ovary to cloaca, and the funnel-shaped abdominal end of the

Fallopian tube opens out on the ovary; i. e., the rich hen's ovary sits right in the funneled mouth of the tube. In the hen, Müller's duct is merely a channel to discharge eggs, and it hardens or calcifies them as they pass the irregularly lumened and tortuous duct. The Müller ducts in a chicken do not coalesce, so that it acts in the hen as a vagina, uterus and Fallopian tube while it is only one channel. But the hen's duct is lined with peculiar epithelium, and secretes albumen to coat the egg and calcium salts to protect it with a shell while the egg passes the duct, which lasts from one to three days. A hen has, curiously, only one Müller's duct and one ovary—the left. The right has atrophied. Dr. Lucy Waite reported to me that while investigating the genitals of hens, she found remnants of the right atrophied Müller's duct in the form of dilated cysts near the cloaca. I had also found similar vestigial remains of the atrophied right Müllerian duct in hens. At first I thought it was unique in birds to have one Müller's duct atrophied and only one duct and ovary functioning; but on further investigation it was found that several of the lower species of animals had the same non-symmetry of ovary and Müllerian duct.

The explanation of the bird's loss of the right ovary and ova duct is not yet given. A very interesting subject was found in the varying upper or abdominal end of Müller's duct. In the pig, Müller's duct ends in an enormously wide, fringed funnel. This large funnel opened into a spacious peritoneal pouch in which lies the pig's ovary. In the ovulation of the sow the ova drop either, first, into this large peritoneal pouch and then into the funneled mouth of Müller's duct, or the ova drop directly into the mouth of the duct. In either case when the sow ovulates it is hardly possible to lose any ova on account of the peritoneal pouch. In animals with multiple births nature provides large means to secure rich supplies for reproduction through the peritoneal pouch and the peculiar ending of Müller's duct. There is a peritoneal pouch in many animals—e. g., cat, dog, mouse, pig—in which the fimbriated end of the Fallopian tube opens. The pouch is peculiar in each animal. The peritoneal pouch decreases in animals up to man. There is a small trace of a peritoneal pouch in woman which I have several times observed. In all animals which I have investigated—sheep, dog, bird, cow, monkey, cat, man, there is a band of muscular or ligamentous structure which connects the fimbriated end of Müller's duct to the ovary. Ascending in the scale of animal life, we have, first, the eggs simply drop out of a hole in the peritoneum; second, the peritoneal pouch exists; third, the mouth of the duct surrounds the ovary, as in birds; and finally, the ligamentum ovaricum persists as it is in monkey and man. This little strip of muscular tissue which connects the mouth of Müller's duct to the ovary, shortens at menstruation or oestrus in all animals which I have examined. In shortening it draws the mouth of the duct over the surface of the ovary, and that part of the ovarian surface which is ovulating may emit an ovum into the duct's mouth; but if the ovulating surface of the ovary lies outside of the mouth of the duct, the ovum may be lost. In the cow as well as in the living woman, I have seen the wide mouth of the tube cemented to the ovary at its circumference by sticky mucus at menstruation. The disappearance of the peritoneal pouch is in direct ratio to

the disappearance of multiple births. The typical sample of the peritoneal pouch at the end of the tube is the pig, which has a typical multiple birth. In man the peritoneal pouch at the tubal end is least, and typical single births characterize the genus homo. So that multiple and single births have some relation to the connection of the ovary to the mouth of the tube. Müller's duct varies widely in its form and coalescence from the lower animals to man. In some the two ducts do not coalesce; e.g., birds; in some they coalesce but a little; e.g., pig, cow and horse; in monkey and man we note that Müller's ducts coalesce for their lower two-thirds; i.e., up to the Fallopian tube.

One very valuable landmark to distinguish the uterus from the Fallopian tube was given to us by the immortal Virchow; that is, the round ligament. The round ligament inserts itself in the duct of Müller at the junction of the uterus and Fallopian tube. This means that all gestation is done in that part of Müller's duct posterior to or below the insertion of the round ligament. Gestation is never done in the Fallopian tube of animals but in the horns of the uterus. In a long search I have never known an authenticated case of tubal pregnancy in any animal below man. Only, so far, has it been demonstrated that in woman tubal pregnancy occurs. It would appear that a monkey was just as liable to tubal pregnancy as woman, from the structure and shape of the genitals, but no proof is yet recorded of tubal pregnancy in monkeys. It would be interesting to note the various kinds of placenta that the Müller duct bears, but space forbids. Suffice it to say that in the carnivora it is zonular; i. e., it reaches all around the circumference of the duct or gestation sac in the form of a band. In the herbivora the placenta is cotyledonous; i. e., the placenta rests on peculiar elevations of the gestation sac, shaped just like a mushroom on its stalk. In the omnivorous; e. g., the pig, the placenta is universal; i. e., the choroidal membrane lies close against the mucous membrane of Müller's duct or the gestation sac. In the quadrumana, as in monkey and man, the placenta is discoidal; i. e., the part of chorionic membrane which nourishes the child lies on the mucous membrane in the form of a disc. Müller's duct acquires various kinds of epithelium for a lining through the animal kingdom. Where the ducts coalesce into vagina, uterus and Fallopian tube as in most higher vertebrates there are generally three kinds of epithelium membrane, as, e. g., squamous for the vagina; glandular, columnar and ciliated for the uterus; and glandular, columnar and ciliated for the Fallopian tube. But whether the duct coalesces or not, a certain part of its epithelial lining possesses peculiar properties of secretory powers. In the bird the endothelium can secrete albumen and calcium salts. In mammals it possesses the power to gestate. In general, the ova may be viewed as a gland and the Müller's tube as its duct.

2. The second stage of the Wolffian body is known as the middle kidney or mesonephros. Its duct is known as the segmental duct or Wolffian duct. The Wolffian duct and the Müllerian duct appear to me to be formed side by side. Others assert that the segmental duct splits into two and thus is formed Müller's and the Wolffian duct. The middle kidney or mesonephros and its duct probably functionates in the human fetus for six weeks. In the pig the mesonephros functionates for about one-half its fetal

life. The middle kidney is the Wolffian body proper of vertebrates and it grows to a very large size. It consists of an elongated body lying on each side of the vertebral column and reaching from diaphragm to rectum or cloaca. One can easily see its long white duct running from its anterior end to its posterior end where it empties into the cloaca. At right angles to this long duct which collects the urine, may be seen dozens of short tubes running into the long tube. The chief portion of the Wolffian body is composed of these small coiled tubes. The duct of the Wolffian body first carries urine; finally it atrophies in woman and the functionless remnant is known as Gartner's duct. In the male it is transformed from a urinal duct to a channel to carry semen—the vas deferens. Nature is conservative and utilizes already formed structures for additional higher functions. Another feature is demonstrated, in that the urinary organs and genital organs are very intimate in their development and growth. For example, the kidneys, ovaries, tubes, uterus and vagina arise from the same Wolffian body; then their food, lymph and nerve supply must be absolutely connected. This principle of same nerve supply is applicable all through adult life and can be observed in many diseases; i. e., a diseased ovary will affect the kidney or a diseased tube will disturb a kidney, by reflex action through its circle of nerves.

The middle kidney or mesonephros, is of the highest interest to the gynecologist, because he has to deal with its vestigial remnants. In woman, the whole middle kidney atrophies and its residue is known as the parovarium. The remnants of this kidney were discovered by Dr. Rosenmüller in 1891. The name parovarium was given to it by Dr. Kobelt.

The mesonephros has shrunk to a trapezoid shaped organ and lies in mesosalphynx; i. e., between the ovary and Fallopian tube. Its pointed or smaller end runs to the lumen of the ovary. It is composed of from eight to thirty tubules which run in a vertical direction. These tubes are the uriferous tubules of the mesonephros. The tubes all pursue a course at right angles to a longitudinal tube known as Gartner's duct—the original ureter of the mesonephros. The parovarium consists of three quite distinct parts: (a) Gartner's duct. This runs toward the uterus and in cows it runs near the mouth of the urethra, occasionally. It no doubt represents Skene's tubes. In the pig it is often many feet long and as large as a clay pipestem. It has a large lumen in the pig, and I have frequently noted its atrophy at different intervals of its course, so that it represents beads strung on a string. It shows also interrupted atrophy in the woman. I have several times, in laparotomy, seen Gartner's duct dilated; once to the size of a child's head, and again I saw it dilated as large as an apple and the dilations were strung along like beads. Perhaps each dilatation represented the entrance of a uriferous tube.

b. The chief remnant of the mesonephros is the vertical tubules of the parovarium, varying from five to thirty, visible to the naked eye. To see the tubules one should hold the broad ligament up to the light. These little tubules frequently dilate into cysts from the size of pin heads up to that of a child's head. The tubules have a lumen lined with epithelium.

c. The third structure found in the remnant of the atrophic mesonephros is that known as Keibel's tubes.

These are flask-shaped cysts or dilated parts of the uriniferous tubules situated external to the vertical tubules. They frequently dilate and gradually acquire a long, thin pedicle. The reason of the existence of these blind, flask-shaped tubes of Keibel must be the same as that for the hydatid of Morgagni.

d. Besides these three distinct structures, we find other relics lying in the broad ligament in the form of isolated cysts lying under the peritoneum. But they have definite locations, e.g., some are nearly always found at the upper border of the abdominal tubal sphincter. Another place is along the tubal fimbriae which connect the tube to the ovary. They are all remnants of the mesonephros. The parovarium has pathological cysts in it in 60 per cent. of women according to my examinations. I have performed laparotomy for parovarian cysts on women from 23 years up to 55 years. Parovarian cysts do not develop before puberty, but they may develop as long as the woman lives after puberty. The repeated rupture and refilling of parovarian cysts I have noted in my own patients. No peritonitis occurred. Sows have parovarian cystic degeneration. One distinguishes a parovarian cyst from other cysts by its capacity of being peeled out of the broad ligament.

3. The third stage of the genito-urinary bodies is known as the metonephros or adult kidney. Its duct is the ureter. The last kidney grows out just behind the mesonephros. It starts as a little white body, and soon grows to a large size. It has at first a spiral, crooked ureter, but as the bladder sinks down into the pelvis it straightens out. The atrophy of the middle kidney and the hypertrophy of the third is a fascinating subject. The blood stream is simply turned from the middle kidney to the last kidney; the one shrinks and the other grows. The mesonephros simply pales from lessening blood; the metonephros reddens from excess of blood. The mesonephros atrophies and the metonephros hypertrophies just by changing the blood current. It may be observed that the duct or ureter of the first kidney persists in woman as Müller's duct, making the vagina, uterus and tube. In the male it is the duct or ureter of the second kidney that acts as the vas deferens and epididymis to carry semen.

By slitting open the abdomen of fetal pigs in various stages one can observe the beginning and course of the ovary. It arises from the internal sides of the Wolffian bodies as a white spot as large as the head of a pin. It is very vascular and very glandular. It grows rapidly from a kind of large, luxuriant epithelium heaped up into a ridge named the genital ridge. It is highly supplied by nerves and lymphatics. It does not manifest sex until the tenth week in the human, and acts similar in the lower animals. One can tell sex by the external genitals far sooner than by the testicle or ovary. The ovary soon after the first three months begins to manifest its Graafian follicles, and it is always seen to be a cystic organ. It sinks down in the pelvis and its artery, the ovarian, stretches out and becomes very long in the upright animals. The ovarian arteries arise from the aorta, just below the renal, at the original site of the growth of the ovaries. The Wolffian body is held to the diaphragm by a strong ligamentous cord which may be called the diaphragmatic ligament. The body is also fastened to the groin by a process which is surrounded by peritoneum like the ferrule on a fork handle. This process of tissue

becomes the round ligament, while the peritoneum which surrounds it becomes the canal of Nuck. This process of round ligament formation with Nuck's canal can be observed to perfection in the growth of fetal pigs. It may be observed that adult kidneys of many animals are lobulated: the reason of this is that the adult kidney arose first in a lobular or separate form. Each lobule was fed by an artery, so that even in adult animals some kidneys may be found with several arteries. The kidney of a human fetus I have seen lobulated but it soon gets smooth. In man, dogs, pig, sheep, etc., the kidney is smooth, and in 75 per cent. it is fed by one renal artery. Among some fifty human cadavers which I have carefully dissected I found that 25 per cent. of the kidneys had two to five arteries. In the cow, one can see the typical lobulated kidney which must originally have had an artery for each lobule. The Wolffian body was originally generally drained by one vein and that would be the renal vein. But the upright position of man and monkey has induced the ovary to fall into the pelvis and this lengthened the ovarian vein. This ovarian vein originally opened into the main vein which would be the renal. At present the left ovarian vein opens at right angles into the renal vein and it represents the original fetal life. But the right ovarian vein opens at present into the vena cava just below the renal vein. Now the explanation I offer for this is that the evolutionary changes have occurred on the right side by the upright position, as then the ovary would drag on the ovarian vein and finally it would be apt to enter lower down in the long vena cava, while the left side still retains its original fetal condition. Gegenbaur explains it in another way by saying that the left ovarian vein is a remnant of the cardinal vein; considerable disease is due to the difficulty of venous return on the left side. The supra-renal bodies, which develop with the genito-urinary, lie in the still unknown field of physiology. They have some relation with the sympathetic nerve whose significance is yet unknown.

1. Out of the Wolffian body arise the uterus, vagina and Fallopian tube. The ovary, parovarium, kidney and supra-renal bodies come from the same source. Hence they all have a physiological and anatomical connection.

2. The genital and urinary organs arise from the same source and occasionally one is modified to act for the other.

3. Since the whole of the genital and urinary organs have both an anatomical and physiological relation, the essential knowledge for the gynecologist will lie in the nerve connections, for disturbance in one organ will disturb the balance of all.

4. Injury to the nerves in one organ will disturb the circulation and nutrition in the other by reflex action.

5. The peritoneum and genitals are anatomically and physiologically connected. Hence disturbance in one will disturb the others.

6. The chief nerve supply of the genitals and urinary apparatus is sympathetic.

7. The main pathology of the sympathetic nerve is reflex action which will disturb any distant or adjacent viscera.

8. The irritation in pregnancy passes up the hypogastric plexus to the abdominal brain and is reflected out on the renal plexus, inducing albumen in the urine. The aching back in menstruation is accounted

for by the close nervous connection of genital and urinary organs. The renal plexus and the autonomic ganglionic chain is dragged on by the hypogastric plexus.

9. The nephritis and albumen in the urine after vaginal hysterectomy is due to the wounding of the hypogastric plexus and ovarian plexus, and the irritation is reflected into the renal plexus disturbing the kidney. The shock from abdominal and vaginal section is due to the damage inflicted on the sympathetic plexus, and is often manifest in kidney disturbance.

10. The intimate anatomical and physiological connection of the *peritonsils, kidneys and peritonium* by nerve, blood and lymph supply invites dangers to one by wounding the other. The danger of disturbed balance is brought about by reflex action flashed from one organ to another through a reflex arc.

11. The anterior and posterior columns of the vagina represent the remnants at the points where the ducts of Müller coalesce, producing thick columns of tissue.

DOMESTIC CORRESPONDENCE.

Does Tuberculin Scatter Tuberculosis?

AN OPEN LETTER TO DR. HEATWOLE OF GOSHEN, IND., FROM DR. DENISON OF DENVER, COLO.

Dear Doctor:—The following are two extracts from the *Goshen Daily News* of Sept. 4, which some one has kindly sent to me. The cuttings are here transposed from their relative positions in the obituary notice, "A good citizen gone," so that the postmortem, which is what I wish to discuss, comes first:

A POST MORTEM.—This forenoon Dr. Heatwole conducted an autopsy on the body of the late George N. Thomas, ascribed by Drs. Fox, Latta, Ash, Irwin, Miller, Johnson and Whitmer. It confirmed the diagnosis of the case, and revealed the fact that the Koch treatment had stopped the progress of the disease on the lungs, but had scattered it all over the glandular system, finally attacking the spine and brain which was the immediate cause of death.

"The growth just under the knee proved to be a solid gland, five by seven inches, and had invaded the knee to such an extent as to entirely destroy the joint, the ends of the bones of the knee joint having entirely disappeared.

"He had been a great sufferer for nearly three years, and especially so for the past few months, which he bore bravely and hopefully, although recovery was hopeless. About seven years ago a growth of a tumor appeared on his leg just back of the knee, caused by tuberculosis. The growth increased gradually, but not until about three years ago were his lungs affected, since that time he has traveled in climates which promised benefit, but improvement was only temporary. Although he took the Koch treatment and it apparently healed his lungs, yet the growth on his leg was constantly increasing in size until the leg became as large as his body and very painful. A few days ago tuberculous meningitis developed, becoming so severe on Saturday that he became unconscious that night, in which condition he remained until his death."

Prompted by a desire to do justice to a most useful remedy (tuberculin) I am persuaded to write you.

For it has seemed to me that we ought to blame ourselves more and the remedy less, and then there would be hope of our becoming well acquainted with tuberculin and its *modus operandi*, as well as that of the disease it antagonizes, to use it intelligently and with good results. The medical profession must be introspective and look to tuberculosis as well as to the composition of the remedy, for an explanation of the so-called "failures" of tuberculin. The delusion, which hinders a thorough understanding of the remedy, is that it inoculates with tuberculosis, or the above inference that it spreads the disease. Whenever *insufficient diagnosis, unsuitable conditions for a cure, and excessive use of tuberculin*, such as obtained in the unfavorable results in the Johns Hopkins and the Pennsylvania hospitals,—whenever these conditions are behind the so-called "failures" I feel like nailing the evidence where it belongs. This is my reason for wishing to review this case of my former patient, Nov. 1892 to March 1893, to see if this dissemination of tuberculosis

through the glandular system is substantiated by the results of the administration of the remedy. I am sure that you will agree. On this point it seems to me there are many theories, and why the stated conclusion of the autopsy is so erroneous, of course I want to admit that this may be merely a *hypothesis* of a newspaper reporter, but it expresses a popular prejudice and a misconception taken by many physicians inexperienced with this new method of treatment, which position is not easy to combat with our insignificant knowledge of tuberculosis and tuberculin. The three reasons are:

1. The tumor in the popliteal space antedated the appearance of any lung lesion whatever by three years. I deem it unnecessary to refer to the frequency with which tuberculosis originates in other parts before manifesting itself in the lungs. Of course there may be a question raised as to the fact, but I am going to assume that the nature of this tumor, as stated in the account, was unique all the time from its beginning; i. e., tuberculous, because under tuberculin treatment it grew hard and there was an effort to contract or shrink, and because the postmortem evidences showed that the most prolonged existence of tuberculosis was in the joint underneath the tumor. I had my good friend Dr. C. Theodore Williams of London, when he was visiting us last November, see this patient. When the doctor felt the tumor he exclaimed: "Oh! lymphadenoma; there is no question about it." All of which would go to show that tuberculosis was behind the lymphadenoma, and served to confirm in my own mind a theory I have had for some time; that *the bacillus of tubercle is not the beginning of tuberculosis*. Instance our general inability to find the bacillus in glandular tumors known to be tuberculous by tuberculin reaction or otherwise, or in adenoid growths in the region of the third tonsil which I have known to be removed, as simply adenoid, from those who were steadily advancing in the tubercular process, as subsequent history proved.

2. The implication of the glandular system antedated the use of tuberculin in this case, and may have been a resultant of la grippe two years previous. I have known of other supposedly tuberculous subjects in whom the influenza seemed to center the tubercular poison in the glands of the neck. In this case both the thyroid glands were becoming much enlarged, there were nodular glands above the clavicles and both breasts were tender and as large as a young maiden's.

3. The reaction to tuberculin was not only in the affected lung, but in all these affected glands, especially in those above the clavicles, the breasts and in the tumor under the knee, showing that there was tubercular contamination there before tuberculin was given. In the case of the tumor on the leg, the size of which was 7½ inches, measured lengthwise with the limb, and 10½ inches across the center, the effect of the treatment was a hardening of the soft mass and a restraint of its growth during the continuance of the tuberculin injections. The pain caused there was a positive hindrance to the use of the larger doses of tuberculin. This was the principal reason, probably, why Mr. Thomas gave up the method at two different times although in all other respects the effect was quite favorable. At one time he almost agreed to the proposition, which the autopsy now proves would probably have been best, namely, to amputate the limb and continue the immunity producing effect of tuberculin. It was with a view of settling this question that Mr. Thomas wished to consult with Dr. Senn, and I was glad to have him do so, but of course did not expect Dr. Senn to take my view of an operation with his expressed opposition to the use of tuberculin.

I think I have made out my case that in this instance the scattering to the glands had occurred before the tuberculin

treatment was commenced and therefore was not due to it.

That the final breakup, which must come, of course, sooner or later, was through the climax in tubercular meningitis is not strange. I have now seen nine cases where the lungs were more or less completely healed through climatic influence, and death came through tubercular meningitis, usually from some intercurrent exciting cause. It is, perhaps, pertinent to this particular affection of a joint for me to add that the young lady who Mr. Thomas will remember as coming to my office on crutches for tuberculin treatment, and who had had tubercular arthritis of both knee joints for about four years, so that she had not stepped on the floor for over two years, has so fully recovered that I hear of her in her Vermont home as walking to church even without a cane. Other cases of glandular tubercular implication have done excellently well, but there is, of course, a necessity for a more persistent or prolonged course than when the glands are not affected, the same as with partially healed pulmonary cavities where the multiplication of tubercular bacilli is with difficulty prevented. While I am on this subject of tuberculin, I wish to say here what I could not, when I wrote my paper a year and a half ago for the American Climatological Association, namely that I have found Kleb's Tuberculocidin to answer excellently well in some febrile, erythric and sensitive cases where the real tuberculin (Koch's) would be inadmissible. It is about one-fortieth the strength of the latter and does not increase a previously existing fever as tuberculin does. However, the descriptions of its preparation and directions for its use are criticised as not being very lucid. I very much wish that some of our bacteriologists this side the Atlantic ocean would take hold of this matter and reasonably supply us with these useful preparations.

Finally, Doctor, I wish to remind you that frequently disseminated tuberculosis, as several cases I have diagnosed by tuberculin injections would seem to show, does not manifest itself in the lungs until the system is profoundly under the influence of the disease. Furthermore, the final dissemination to the glands, in most cases of tuberculosis ending in death, comes at that period when the individual vitality is lowered to the point where resistance is exhausted, and where it is unreasonable to conclude that any other agency scattered the tuberculosis to the glandular system.

Very respectfully yours,

CHARLES DENISON.

Has Practiced Abroad, but does not Specify His College.

To the Editor:—As the JOURNAL is looked to abroad as the exponent of American medicine, is it not likely that foreign medical boards will think that our Association approves of inferior medical colleges, when some of the very worst in the United States are given constant advertising space in the JOURNAL, thus injuring all American diplomas? Having practiced for some years in a foreign country I know with what contempt the "Yankee" M.D. is held, and this is because of the shameful ignorance shown by most of our graduates who have left our shores seeking fame or fortune in foreign climes, and who, of course, were always from inferior colleges.

Yours, etc.,

D. C. NEWMAN.

Can Get All the Cerebrin He Wants.

To the Editor:—Dr. G. Archie Stockwell can get all the "cerebrin" made in May, 1903, he wants, and for nothing, provided he will, under the eyes of three physicians to be selected by the editor of the JOURNAL, repent with it the

experiments on himself which he alleges in the *Medical News* of Aug. 26, he performed. Satisfactory evidence will be given that the "cerebrin" is of the date mentioned.

WILLIAM A. HAMMOND.

To Whom Credit is Due.

To the Editor:—In your issue of Sept. 16, there appears a letter from Dr. Hinde, in which he calls attention to a certain oversight in giving due credit for our joint report of a case, "Periodically Recurring Oculo-motor Paralysis." The facts are that Dr. Hinde first saw the case and credit is due him alone for having differentiated this rare condition. The case was shown me and I subsequently made an exhaustive study of the bibliography which, with the notes of the case formed the first paper published in the *Medical Record*. No one regrets more than myself the fact that Dr. Hinde has not been credited with this interesting observation, and I now wish distinctly to state that I had nothing to do with the case further than that I examined it, studied the literature, and wrote the first paper.

Dr. Hinde says in closing that credit ought to be divided in this case. I think not, as it belongs exclusively to him.

Very truly yours,

HAROLD N. MOYER.

NECROLOGY.

Dr. W. C. Wardlaw, died in Atlanta, September 2. For many years Dr. Wardlaw has been practicing his profession in Augusta, Ga. He had been elected Dean of the Dental College at Atlanta, and had just moved to that city, preparatory to assuming his new duties.

He was prepared for the South Carolina College, in the village school where he was graduated, and afterwards attended lectures at the Charleston Medical College, intending to make medicine his profession, but, the war coming on he was obliged to suspend his studies, and enlisted in the services of his State, and it was here that Dr. Wardlaw displayed that endurance, courage and heroism which endeared him to his men, and called forth the commendation of his Commanding General and the compliments of his Colonel.

He was desperately wounded during the war, and from the effects of that wound it was said he never recovered, and that his death was attributable to it.

Returning from the war shattered in health and empty in purse he determined to adopt dentistry as his profession, a calling to which his great ingenuity and former knowledge of surgery well fitted him. After practicing his profession in Abbeville for several years, subsequent to the war, he moved to Augusta, and rapidly rose to prominence in his profession.

Dr. Charles L. Dayton, one of Buffalo's best known physicians, died Sept. 7, at his residence on Dearborn street after an illness of about ten days. Typhoid enteritis is said to have been the immediate cause of death. Dr. Dayton was born in the town of Eden, New York. He was graduated from the Buffalo Medical college in 1851 and established a successful practice at Black Rock which continued for nearly forty years.

He was a brother of Dr. Lewis P. Dayton, ex-mayor of Buffalo, and many years ago he held the position of health physician of Buffalo. He was a member of the Erie County Medical society, and also of the Occidental lodge of Masons.

Dr. Robert Ferguson, at Anderson, Indiana, Sept. 10.

THE Journal of the American Medical Association PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, IN ADVANCE, PER ANNUM, IN ADVANCE, \$5.00
SINGLE COPIES, 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 6 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the
Treasurer, RICHARD J. DUNCLISON, M. D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or National Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunclison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 23, 1893.

THE NEED OF ORGANIZATION.

The daily press are just now engaged in a crusade against our colleague, MR. ERNEST HART, for his outspoken speeches against telepathy, theosophy, hypnotism, Keeleyism and homeopathy. It seems that whenever there is opportunity, the press generally take the side opposed to the professional view. This fact can not well be controverted. But it is scarcely fair to the press to accuse them, as MR. HART has, of having a moneyed interest in charlatanism. The truth is that the real fault lies with the medical profession itself. The average State medical society scarcely contains ten per centum of the profession within the State. The average legislator therefore hastily concludes that the medical society is the profession—that there are none outside except the irregulars, and he very naturally infers that the irregulars constitute a large proportion of the medical practitioners. He thereupon passes laws giving representation on State boards of health and other bodies to all descriptions of medical heretics and charlatans. If the medical profession will only organize by union with their local, State and National medical associations, they will show their real strength. No politician can afford to ignore organizations controlling so many votes, and there can be no doubt but much of the official misrepresentation to which the profession has been subjected will cease when the eligible members of the profession unite.

The effect upon the press of thorough organization would be no less striking than its effect upon the political class, and a timely intimation that the united medical profession had, by a duly constituted committee, investigated the subject of "—ism" and found it wanting, would put a brake on such notoriety: except, perhaps, that embodied in paid advertisements; and even these may be suppressed later through the gradual enlightenment of public opinion. A united medical profession can mold public opinion on all professional topics.

These are among the reasons why organization is so desirable and so necessary. That the medical men of this country are beginning to act upon this conviction, we have evidence in the steady increase of membership in the AMERICAN MEDICAL ASSOCIATION. Forty-one new members were added last week, and there were ten restorations to membership in the same week. The increase in the membership, including those who joined at Milwaukee, for the three months ended August 31, is 351. We added this week one hundred and twenty copies to our mail list. We sincerely hope that the good work may be actively pushed by every member of the Association, so long as any of the one hundred thousand physicians remain out of the fold. Blank applications can always be furnished by the JOURNAL, and will be sent to any member who desires them in such quantities as he may wish.

CHARAKA-SAMHITA.

The oldest of the Hindu medical books known to be complete, the Charaka, is undergoing translation at the hands of the learned DR. AVINASH CHANDRA KAVIRATNA. The sixth fasciculus of the Charaka lies upon our table. The difficulty about ancient Hindu literature is the absence of dates, the Hindu chronology being utterly fabulous.

The laws of hygiene and of diet, however, have been studied by the Hindus from the earliest times. The Ayur Veda, the "science of life," is the oldest of their books, and as was customary in all oriental mythology its origin is said to be divine, having been prepared by BRAHMA in the Satyar-yuga.

Wise, in "History of Medicine Among the Asiatics," gives the following list of authors:

AUTHOR'S NAME.	NAME OF THE WORK.	
	EUROPEAN.	INDIAN.
Ashtanga	Ashtanga	Ashtanga
Agnivesa	Agnivesa	Agnivesa
Charaka	Charaka	Charaka
Bhishag	Bhishag	Bhishag
Jatya	Jatya	Jatya
Parasara	Parasara	Parasara
Harita	Harita	Harita
Kashyapa	Kashyapa	Kashyapa
Devadatta	Devadatta	Devadatta
Susruta	Susruta	Susruta

These works are all compiled on the plan of the Ayur Veda.

The Charaka is a system of oral instructions delivered by AGNIVEṢA (or AGNIDESA) and commented upon by CHARAKA. The work is compared to that of HIPPOCRATES, and Wise asserts as a strong probability that much of the Hippocratic knowledge was derived from the Hindu pre-existing work.

The origin of modern science may be traced in the oriental mythology, which narrates that, upon a time, when the world was young, the sages were brought together to read their books of medicine for purposes of comparison and adoption. That of the sage AGNIVEṢA received such approval, that

"with a voice which reached to Heaven" the assembled sages proclaimed their admiration.

Years rolled by, and CHARAKA corrected and revised the work of AGNIBHSA which then became the exponent of Brahminical medical lore.

The directions translated in the present fasciculus for the construction of a hospital are interesting:

In the first place a mansion must be constructed under the supervision of an engineer well-versed with the science of building mansions and houses. It should be spacious and roomy. The element of strength should not be wanting in it. Every part of it should not be exposed to strong winds or breezes. One portion at least should be open to the currents of wind.

It should be such that one may move or walk through it with ease. It should not be exposed to smoke, or the sun, or dust, or injurious sound and touch and taste and form and scent. It should be furnished with staircases, with pestles and mortars, privies, accommodation for belting, and cook-rooms.

After this, should be secured a body of attendants of good behaviour, distinguished for purity or cleanliness of habits, attached to the person for whose service they are engaged, possessed of cleverness and skill, endowed with kindness, skilled in every kind of service that a patient may require, endowed with general cleverness, competent to cook food and curries, clever in bathing or washing a patient, well-versed in rubbing or pressing the limbs, or raising the patient or assisting him in walking or moving about, well-skilled in making or cleaning beds, competent to pound drugs, or ready, patient and skilful in waiting upon one that is ailing, and never unwilling to do any act that they may be commanded (by the physician or the patient) to do. A number of men should also be secured that are skilled in vocal and instrumental music, in hymning encomiums and eulogies, conversant with and skilled in reciting verses and pleasant discourses and narratives and stories and legendary histories, clever in reading the face and understanding what is wanted by the patient, approved and liked by him upon whom they are to wait, fully conversant with all the requirements of time and place, and possessed of such politeness as to become agreeable companions. The mansion should also be stored with an adequate supply of *Lāya* (oil), *Kapinjala* (oil), *Caca* (oil), *Harina* (oil), *Ena* (oil), *Kālapuchi*, *cebaka* (oil), *Mrigamūtrika* (oil), and *Yrabhra* (oil).

A cow also should be kept, yielding copious milk, of a quiet disposition, healthy, having all her calves living, well tended with food and drink and kept in a fold that is properly cleaned. So also should be kept little vessels or cups, larger vessels for washing the hands and face, water vessels or jars, small jars or pitchers, dishes, metallic or earthen jars, caldrons or pans, larger and smaller jars, vessels called *kanalas*, hollow vessels for covering articles, wooden or metallic ladles, mats, covers of cloth or blankets, vessels for boiling oils and ghee, churning rods, deer-skins and sheepskins, rugs, cloths made of cotton and wool, strings and chords, beds and seats, vessels called *Rhinopterus* full of water and flatter vessels for holding spittle and evacuations, all placed ready for use, good beds placed upon bedsteads and overlaid with white sheets and containing pillows, for use when sleep is needed, beds and carpets for lying down or sitting upon, articles necessary for the operations of *Sauha*, *Sauha*, *Tanaka*, plasters, fomentation, rubbing, vomiting, purging, application of oil or other kinds of enemata, erubines, urination and passing of stools, well washed mulbers, and flat stones that are smooth and rough and neither smooth nor rough, and diverse kinds of instruments, domestic and surgical. Smoking tubes, enemas, and enemas of a special kind called *atracastibala*, brushes and brooms, bal-

ances and weights, measuring vessels and baskets. Ghee, oil, fat, marrow, honey, treacle, salt, fuel, water, honey-wines, sour gruels of different varieties, different kinds of wines, whey, butter-milk, sour gruel of paddy or rice, and the different varieties of animal urine, should also be kept ready.

We have not space to give any more of this most learned and ancient production of the Hindus, at this time, but we can here only express our admiration, alike for the scholarship of DR. AVINASH KAVIRATNA, and the industry which has produced the work, and as well the liberality of the publisher.

CANNED VEGETABLES.

The Chemical Division of the United States Department of Agriculture has just issued another part of its Report on Foods and Food Adulterants, technically known as Bulletin No. 13. The present issue, Part VIII, deals with canned vegetables, especially with regard to methods of preserving, the preservatives employed, the character of the vessels used and the food value and digestibility of the articles. A few words concerning this report may be of use, inasmuch as owing to the publicity given to it, medical practitioners may be questioned as to their views on the subject. Tin and lead were found, derived from the cans and solder; copper from salts of the metal used for "greening" the vegetables; zinc in some samples of French goods, and sulphurous and particularly salicylic acid, employed for their antiseptic properties. Boric and benzoic acids, saccharin and hydronaphthol were not found in any of the samples examined. Tin is the most common metallic contamination, being present in every can that has been put up for any length of time. Tin poisoning from the use of canned goods is not often alleged, although HEHNER and other experimenters have found stannous hydrate to exercise a marked poisonous action on guinea pigs and other small animals. Lead is freely used by the packers both in the solder and in low grade tin plate; but there is little danger of lead poisoning by the use of canned goods, for tin precipitates lead from its solutions and lead is not attacked by acids in the presence of as much tin as is found in the tin plate used. There is more danger of lead poisoning from the sheet lead tops of glass jars than from the solder or lead of the tin cans. The quantity of copper needful for "greening" amounts to only a quarter of a grain per pound, but much more than this quantity was often found. The temperature required to destroy spores in vegetables tends to disintegrate many of them and render them less attractive in appearance; hence the use of salicylic acid. Doses of one-half to one and a half grams of this acid have been given and taken daily by experimenters for periods of many months without affecting the system in any notable way. Nevertheless its action on the kidneys is recognized, and in exceptional cases of renal disease its continued ingestion

The meaning is that though not erected against the breeze, or strong winds, one portion of the mansion should be exposed to the breeze. (1)

in the quantity present in canned goods may be harmful. In dyspeptic cases, also, the antiseptics may do harm by interfering with the normal action of the digestive ferments.

A trade journal criticises the report for conveying the impression that there is a widespread use of injurious antiseptics in injurious quantities, and points with emphasis to the fact that over one thousand million of cans are packed and consumed every year in this country alone and no well authenticated case of sickness has been traced to them, which could not with equal force be attributed to the use of similar articles not canned. The chemists, however, do not intend to convey that impression nor to urge a prohibition of the use of copper salts and preservatives; but they claim the right on behalf of the people, of being informed by notice on the label of the can whether any ingredient foreign to the vegetable is present. Packers should not be permitted to use these substances without notice plainly given of their presence and quantity, for the purchaser should be accorded the privilege of electing whether or not he will take the doses.

AN APPEAL FOR PEACE AND TOLERANCE.

The *Boston Medical and Surgical Journal*, August 24, gives prominent place to an article on "Sectarianism in Medicine." Four extra pages appear to have been added to that issue in order that the said article may be printed in its entirety. The peculiarity of the article may be judged from the fact that the author thereof arrogates to himself and his party all the charity and good-will that lies in the possession of our fraternity, while applying to the standard bearers of rational medicine the most hateful of epithets, such as, "bigotry, intolerance, narrowness," also the adjectives, "pretentious and fraudulent." The writer would remodel all medical societies according to an "ideal" of his own conception, without the restraint of ironclad by-laws and codes of ethics, and without any wholesome knowledge whether any such societies have hitherto been tried and found wanting. So far as our knowledge extends, the experiment has been tried once in this country, in the State of New York, but in no other country and no other State. Ten years have gone by, and the organization which threw off the restraints of "bigotry and intolerance" remains about where it was when it started—less prominent, if anything can be judged of it from the outside; the assumption ten years ago, by its leaders, of all the better qualities of heart and mind has really done no harm and has converted nobody. The old paths of rational medicine have not been destroyed, the ethically persuaded members of the profession are still intent upon their errands of mercy, and are ignorant of much that is said and written about their bigotry

and narrowness of spirit. The writer of the article mentioned above, has our thanks for one paragraph, namely, that wherein he reports the term "allopathy," as applied to the rational branch of medical practice. He says: "The impudence of those who would force medical men who do not believe in homeopathy as a general principle, and who refuse to place the slightest limitation upon their practice, to accept the title, allopathy, is colossal." The word "allopathy," and others having the same etymological significance, should be uncompromisingly rejected by every member of the profession; not only as being non-descriptive, but, as conveying a false impression. These terms are not used at the present time to the same extent as formerly, but we even now occasionally meet with them in situations where the audience has a right to expect a purer form of expression.

In conclusion, let us remind the writer that the honorable sentiments of justice, fair play, and toleration are as certainly the characteristics of medical men as of any other body or class of men. It is bad taste and poor diplomacy in one who bears a flag of truce and terms of capitulation to hurl abusive epithets at the heads of those who "hold the fort." Little efficacious work in the way of peace-making can be brought about in this manner.

CLASSIFICATION OF CHEMICAL SALTS AND COMPOUNDS AS PREPARATIONS OF COAL TAR.

The United States Circuit Court of Appeals affirmed May 17, 1893, the judgment of the Circuit Court, reversing the decision of the board of general appraisers in the cases of Roessler & Hasslacher Chemical Co. and W. J. Matheson & Co., Limited, its decisions being now just reported in 56 *Federal Reports*, pp. 481, 482. It holds that the provisions of the tariff act of March 3, 1883, imposing a duty of 20 per cent. on "all preparations of coal tar, not colors or dye," not specially provided for, applies to a product, the determining characteristic of which is something which it has received from coal tar, notwithstanding some of the constituents of coal tar have been eliminated, and other substances added, and that under this rule, naphthionate of soda is dutiable as a preparation of coal tar, and not as a chemical salt, under the subsequent provision of the act, (22 Stat. 494; Tariff Ind. New, par. 92,) imposing a duty of 25 per cent. on all chemical compounds and salts, not specially provided for; while tolidine base and dinitrotoluene are dutiable as preparations of coal tar, and not as chemical compounds, under the subsequent provision of the act.

A GOOD BEGINNING.—Dr. Plummer, the chairman of the Committee of Arrangements at San Francisco, has begun his labors by sending in the names of nine new members by application. This is one of the many evidences of the great movement now going on in building up the Association.

PAN-AMERICAN EXCURSION.

AT BOSTON.

[From the Boston Herald.]

The South Americans and all the other foreigners among the delegates of the Pan-American medical congress, recently held in Washington, who arrived in Boston Sept. 12, had a gay time in their own way as the guests of Boston physicians.

There are about sixty of the visiting physicians, and a good many of them are accompanied by their wives and families.

Yesterday morning they visited the Massachusetts General Hospital, where they were carried from the Brunswick in three or four big transfer coaches.

The Pan-Americans looked like foreigners. Most of them seemed not to understand more than the most commonly used English words and phrases, and Dr. A. Bustillo and Dr. Julis Selva of the Harvard medical school, acted as official interpreters.

The visitors went through the Massachusetts General Hospital under the escort of Supt. Pratt, Dr. Pratt, in describing rooms or instruments or operations, spoke in English, and Mr. Bustillo diffused his knowledge in the sweet toned Spanish tongue.

The party were escorted to Boston by Dr. Adams of Washington, and were met at the depot by Dr. Selva and Dr. Bustillo.

Gen. Ybarra met the delegation later to act as an escort. Arthur P. Cushing, Mexican consul, and his brother, Dr. E. W. Cushing of Boston, were also at hand to do their part in entertaining.

The visitors while here are the guests of the Massachusetts Medical Society, the committee of entertainment from which is composed of Dr. J. C. White, chairman, Dr. H. P. Walcott, Dr. S. H. Durgin, Dr. A. T. Cabot, Dr. E. H. Bradford, Dr. J. C. Warren and Dr. R. H. Fitz.

After the party got a pretty fair idea of our hospital they were driven to the Harvard medical school. They all gathered in the dean's room, on the first floor, where Dr. J. C. White detailed the plan for inspection through Interpreter Bastillo.

Two by two the Pan-Americans went from the bacteriological exhibit room down stairs to the dissecting room on the top floor.

Some found departments they liked, and made long stops, having everything explained.

Shortly before 1 o'clock the ladies of the party arrived at the medical school. They had been entertained by Gen. Ybarra and Mr. Cushing, the Mexican consul, and thoroughly enjoyed the drive about the city and suburbs.

The ladies and children were most pronounced brunettes. A few of them resembled the typical Brazilian maidens of the dark-skinned, dark-haired types, like the Misses Mendonca, daughters of the Brazilian minister in Washington during the last administration.

At 1 o'clock all the delegates and their families sat down to lunch in the medical school.

Wednesday, Sept. 13, the program for the delegation was to visit the City Hospital from 9:30 to 12:30; and from 1 to 6, at the invitation of the Boston board of health, they visited the sanitary and quarantine stations in the harbor.

In the morning the ladies were entertained by Dr. E. W. Cushing at his private hospital in Roxbury, and visited with him the Woman's Charity Hospital. Lunch was served at Dr. Cushing's hospital, and then the ladies were taken by Dr. Cushing to join the excursion down the harbor to the quarantine stations.

The party was composed of the following:

Dr. J. C. White, Dr. M. H. Pratt, Dr. Aug. Cornejo, Havana, both to direct the medical and sanitary inspection of the Board of Health, and to act as interpreters of the medical school. Dr. J. C. White, Dr. M. H. Pratt, Dr. Aug. Cornejo, Havana, both to direct the medical and sanitary inspection of the Board of Health, and to act as interpreters of the medical school. Dr. J. C. White, Dr. M. H. Pratt, Dr. Aug. Cornejo, Havana, both to direct the medical and sanitary inspection of the Board of Health, and to act as interpreters of the medical school. Dr. J. C. White, Dr. M. H. Pratt, Dr. Aug. Cornejo, Havana, both to direct the medical and sanitary inspection of the Board of Health, and to act as interpreters of the medical school.

Licaga, president of the Board of Health, San Andres, Mexico; David Contreras, Mexico; Dr. G. Vargas-Paredes, Bogota, Colombia; Dr. J. R. Yrujo, Mexico; Ernest W. Cushing, editor of *Annals of Gynecology and Pediatry*, Boston; Dr. Enrique Lopez, Havana, Cuba; Dr. Francisco Marin, Pueblo, Mexico; Dr. George C. Ober, Washington, D. C.; Dr. Alfredo Garces, Popayan, Colombia; Dr. Olan Mendota, Buénos Ayres, Argentine Republic; Dr. G. Wythe Cook, Washington, D. C.; Dr. George N. Aker, Washington, D. C.; Dr. James G. Meschane, Baltimore, Md.; John A. Homer, Washington, D. C.; Dr. Luis E. Ruiz, Mexico City; Dr. Daniel Gutierrez, Manizales, Colombia; Dr. Juan J. Oliva, San Jose, Costa Rica; Dr. Emilio Echeverria, Costa Rica; Dr. C. H. A. Klein-Schmidt, Washington, D. C.; Dr. George H. Rohé, Catonsville, Md.; Dr. G. L. Magruder, Washington, D. C.; Mr. De Pablo; George E. Kanning, Lansing; Dr. Antonio Jover, Havana, Cuba; Dr. Antonio Mendizábal, Mexico; Dr. J. B. Wolfe, Glasgow, Scotland; Dr. Ernest Hart, editor of the *British Medical Journal*, C. S. Newbrier, Bay City.

With the delegates are two or three Washington physicians and J. E. Jones, secretary of the National Capital Press Club, who represents the Washington *Evening Star*. He is the only press representative traveling with the party.

The party will leave Boston and stop at Saratoga, Niagara Falls, Detroit, Toledo, Cincinnati and Chicago.

AT DETROIT.

[From the Detroit Free Press, Sept. 17.]

The delegates to the Pan-American Medical Congress, which was held at Washington, arrived in the city yesterday morning before 7 o'clock. The party, which numbered about sixty, were principally from Mexico, being accompanied by Samuel S. Adams, chairman of the committee of arrangements; Dr. H. L. E. Johnson, chairman of the transportation committee. They came by special train, which the United States Government has provided for the conveyance of the distinguished party from Washington to Chicago.

At the depot they were met by the reception committee, composed as follows: Dr. E. L. Shurly, chairman; Drs. A. W. Imrie, W. G. Henry, Hal C. Wyman, E. W. Jenks, J. Flinterman, A. E. Carrier, Donald Maclean, Leartus Connor, E. A. Chapoton, P. B. Le Blanc, J. V. Beelaere, T. A. McGraw, H. O. Walker, F. W. Mann, C. Henri Leonard, and Messrs. M. R. Gattel, Herman Freund and F. H. Borradaile, and escorted to the Russell House where they sat down to breakfast.

After a short rest the party were driven in carriages to the extensive laboratory of Frederick Stearns & Co., Twenty-first street, and were there received by Mr. Stearns, Sr., who was awaiting their arrival.

They visited twenty-four departments in the following order: Mill room, fluid extract manufacturing, still room, fluid extract percolating room, fluid extract finishing room, pomade washers, pharmaceutical manufacturing, capsule room, stock room and analytical room, pill manufacturing room and gelatin coating room, sugar coating room, pill mass cutting room, Spanish office, pill finishing room, seidlitz room, pressroom, composing room, and compressed lozenge room, ointments, bottle washing room, filling room, filled stock room, packing and shipping room, cachet room and box factory, and stock room. On the top of each of the doors to the different departments was a large printed card in Spanish describing the department, and the nature of the work performed there. The doorways to the different departments were also decorated with the flags of the nations represented, the Spanish colors being conspicuous.

Special interest was manifested in the manufacture of hard and soft capsules and in the manufacture of pills. The mechanical processes in use were entirely new to the strangers, and when they saw hundreds of pills turned out in a twinkling, as if by magic, and the gelatin of capsules formed, filled with the fluid and hermetically sealed in about the time it takes to swallow one, they could only utter their amazement. They were impressed with the completeness of the lines of pharmaceutical products, with the magnitude of the establishment, its equipment, the system that was apparent everywhere, and the scrupulous cleanliness of every department. It took fully two hours to walk over the building, after which the company were entertained at luncheon in the crude stock-storing room. Time being limited, the refreshments had to be hurriedly partaken of. They left about 12 o'clock.

They also visited the great laboratories of Parke, Davis & Co. and Nelson Baker & Co., where they were courteously received and hospitably entertained. They were then driven round the city and to Belle Isle, and at 2:30 took luncheon at the Russell.

In the evening they were entertained at a banquet at the Russell House. The following day they were given a sail down the river, and left in the evening for Cincinnati.

(Detroit Free Press, Sept. 18, 1893.)

AGROUND IN LAKE ST. CLAIR.—The visit of the delegates to the Pan-American Medical Congress came to an unpleasant ending last night and doubtless many wished they had omitted the last feature of the entertainment. The delegates together with a number of local physicians and ladies took the steamer *Mary*, yesterday morning for a trip through the lake. The party was entertained at the Oakland by Mark Hopkins, but on the return trip the boat evidently lost her way, for she ran in too close to the Grasse Pointe shore and came to a standstill 300 feet from the club dock, running very hard aground. All efforts to release her were without avail, and finally a boat was lowered and some of the local physicians went ashore to make arrangements for bringing the party back. The street car company was apprised of the situation and sent out cars to convey the visitors to the Michigan Central depot, where their special awaited them. It took some time to convey all in safety to the shore, and there was a great deal of consternation among the party while waiting for turns in the small boat. The train was held and the delegates got away, although behind the scheduled time.

AT CINCINNATI.

(From the Commercial Gazette.)

CINCINNATI, O., Sept. 18, 1893.

Mayor Mosby Monday morning received the representatives of the Pan-American Medical Congress. There were about sixty in the body. The delegates arrived in the morning in a special train; stopped at the Grand Hotel for breakfast, and made the City Hall their objective point. They came in a trolley and in carriages, and on alighting took possession of the Mayor's handsome reception room. They had scarcely ensconced themselves in the heavy leather sofas and chairs when His Honor, arrayed in a new suit of black and a shining tile, stepped out of the private office. Dr. J. C. Culbertson, Chairman of the Reception Committee; Dr. Comegys, President of the Academy of Medicine; the Health Officer and several other medical men, members of the Reception Committee, stood around ready to do honor to the distinguished visitors. Dr. Culbertson introduced the Mayor, who shook hands with each of the party, and then all adjourned to the handsome council chamber, where His Honor spoke as follows:

"It is with a great deal of pleasure that I welcome the Pan-American Congress to our city. I extend to you the warmest greeting of our citizens, and I want to thank you for your interest in studying our customs and laws. Such interest is for our mutual benefit, and can not but help uniting the Americas in a firmer union. As for your excursion, I feel and hope that commercial prosperity will follow it. As for our hospitality, I wish to say that the city is yours. If you see anything you want, take it; I will give you even our new City Hall."

The speech ended, the Congress took carriages to the City Hospital, where they went through the wards. The College of Music was next visited, and President Peter Rudolph Neff had everything in good shape. In the College proper all styles of classes were in recitation, and the Lyceum and Odeon had concerts. In Music Hall the great organ was performed upon, and the only audience was the visitors. Leaving the college, the visitors walked to Fourteenth street, where three electric cars awaited them. These were run up Elm to the incline, and up that and on out to Burnet Woods, where the carriages, which had been sent on, took the members through the park and also through Clifton. After a view had been taken of the handsome suburb a cut was made for the Zoological Gardens, where dinner was served.

After dinner Avondale and Walnut Hills were driven through and then Eden Park and at the Art Museum a stop was made and a lunch served. The Rookwood pottery was then examined, and a trip down the incline made. Carriages were in waiting and conveyed the Queen City guests to the Grand, where after supper, the party took a special train for Chicago. With the party was a colored man, Surgeon General for the Republic of Hayti. Another (apparently colored) man was physician to the Khedive of Egypt, and a third, a handsome white man, was the medical adviser to the Emperor of Austria. The two latter do not belong to the Congress, and joined the party accidentally in Washington.

AT CHICAGO.

The excursionists reached the Union depot, Chicago, on Tuesday, Sept. 19. They were met at the depot by a com-

mittee consisting of Drs. C. W. Earle, J. C. B. Hamilton, I. N. Danforth, Truman W. Miller, Randolph N. Hall, Cassius D. Westcott, Frank C. Greene and Geo. Henry Cleveland. This committee had arranged for the whole party at the Palmer House, but one of the Washington committees had arranged for breakfast for them at the Auditorium, but the *entertainment* was obviated by the party going in a body to the Auditorium for breakfast. After breakfast they went to the banquet room, where they were formally welcomed by the Hon. Carter H. Harrison, Mayor of Chicago, who was introduced by Dr. Chas. W. Earle, President of the Chicago Medical Society. The Mayor made one of his characteristic speeches, which was well received.

Dr. Fernando Henrotin then bade the visitors welcome in French, Dr. E. J. Gardner in Spanish, and Dr. John E. Hamilton in English. Having been thus thrice welcomed, a brief response was made by one of the delegates, and the party was allowed to rest until evening.

At 8:30 the hall and reception rooms of Kinsley's were thrown open, and the delegates were received by the General Committee of the Medical Society.

The committee consisted among others of the following:

Dr. Chas. W. Earle, Dr. John E. Hollyster, Dr. Edmund J. Downing, Dr. Nicholas Senn, Dr. Archibald Church, Dr. I. N. Danforth, Dr. S. S. Davis, Sr., Dr. John E. Hamilton, Dr. Truman W. Miller, Dr. D. W. Graham, Dr. J. M. Patton, Dr. R. N. Hall, Dr. E. J. Gardner, Dr. L. E. Ingham, Dr. Edmund Andrews, Dr. Frank Johnson, Dr. Frank Andrews, Dr. Morgan R. Brown, Dr. R. N. Isham, Dr. J. B. Murphy, Dr. H. Kellogg, Dr. LaGrange, C. S. A. Dr. J. P. Wertenbaker, M. H. S., Dr. F. C. Greene, Dr. DeLaskie Miller, Dr. Wylie Andrews, Dr. Frank Edlins, Dr. H. T. Byford, Dr. Sanger Brown, Dr. C. B. Cleveland, Dr. F. C. Hotz, Dr. S. H. Stevenson, Dr. Hoff, C. S. A., Dr. Bayard Holmes, Dr. D. R. Brown, Dr. J. H. Etheridge, Dr. A. R. Reynolds, Dr. W. L. Clark, Dr. E. O. Bolen, Dr. Ernest Hart and Sir Richard Webster.

Many ladies attended the reception. A male quartette sang funny songs, and a mandolin orchestra furnished instrumental music.

On Wednesday the exercises began by a trip to the Chicago Medical College, where the new laboratory was inspected. The party then visited the Cook County Hospital where luncheon was served. Dr. J. B. Murphy presided. There were some toasts, after which the Rush Medical, Physicians and Surgeons, Woman's, Polyclinic and Post Graduate Medical Colleges were visited, and the Presbyterian Post Graduate and Polyclinic Hospitals. The day was finished at the Polyclinic. The visitors were escorted to their rooms at the Palmer House, and the great Pan-American Medical Congress had finished its program.

MISCELLANY.

Gift to a Hospital.—St. Luke's Hospital, Detroit, will receive \$200,000 as a bequest from the late Samuel B. Coyle of that city.

Homeopathic College.—The Louisville homeopaths have started a medical college in that city.

Binghamton, N. Y., hospital has been reopened, the city council having voted the money for its continuance.

New Hospital at Winnipeg, Man.—Winnipeg doctors are making strenuous efforts to have a general hospital established by the Dominion Government.

West Chester Hospital.—The managers of the West Chester county, Pa., Hospital have filed their application for the \$10,000 voted them by the last legislature for the erection of a new building, with proviso that the management should first raise \$5,000.

Pennsylvania Hospital for Feeble Minded.—The site for the State hospital for the care of feeble minded children has been selected near Franklin, Pa.

Dr. P. O. Hooper Resigns.—Dr. P. O. Hooper has resigned his position as superintendent of the Arkansas State Lunatic Asylum, the resignation to take effect some time within the next thirty or sixty days. No reason is said to be given by the superintendent in his letter asking to be relieved of his charge. The Arkansas Insane Asylum is the most important charity in the State.

Dr. Pozzi of Paris, the well known gynecologist, is on his way to Chicago, having been designated by the French Government to attend the World's Fair.

Medical Society of the State of New York.—The following business committee has been announced by the president of this Society, Dr. Herman Bendell of Albany: Dr. Henry Flood of Elmira; Dr. L. Bolton Bangs of New York; Dr. Edward Clark of Buffalo; to whom all communications regarding papers for the meeting of the society in February next may be addressed. F. C. CURTIS, Secretary.

Medical Club Election.—At the first regular meeting of the Roswell Park Medical Club of Buffalo, the following officers were elected for the ensuing year: president, Dr. Julius H. Potter; vice-president, Dr. George F. Cott; secretary and treasurer, Dr. James A. Gibson. Dr. Potter read a paper on diphtheria and its latest treatment.

A Hospital for Melrose, Mass.—A charter has been issued from the office of the Secretary of State for the incorporation of the Melrose Hospital Association. Royal P. Barry is president of the new association, and Decius Beebe treasurer. The hospital will be used for the needy sick and disabled of the town. Those who are in a position to pay will be requested to do so. Money so received will go to the maintenance of the hospital.

Colorado Medical Library Association.—DENVER, COL., Office of the Secretary, July, 1893.—The medical fraternity of Denver and Colorado are endeavoring, as the accompanying booklet shows, to build up a medical library in this city. It is not necessary to call attention to the advantages which accrue to the profession of medicine through the establishment of a medical library. Our remoteness from the centers of population makes the work we have undertaken difficult in many ways. Your society can aid materially in this enterprise by sending us its proceedings. Anything sent us will be acknowledged, placed on the shelves of the library and brought to the attention of its readers.

Yours respectfully,

J. T. ESKRIDGE, M.D., President,
HENRY SEWALL, M.D., Secretary,
J. C. DANA, Librarian Public Library,
For the Association.

Address, care Public Library, Denver, Col. (The association will pay transportation if you wish.)

The State Board of Health of Nebraska.—The State Board of Health Sept. 10 ruled against the issuing of certificates as physicians to graduates of Cotner University medical department, thus upholding the action of the board's secretary. The board has passed this order: "Your report in the matter of the medical college of Cotner University, together with other papers touching the same matter, having been under consideration of the State Board of Health, you are hereby notified that we affirm your decision and coincide with your conclusions that the number of clinics in connection with the college has not been sufficient to justify the recognition of its diplomas, and we further recommend that as soon as this college has, in your judgment, complied with the requirements of the statutes its diplomas be recognized, and that all due encouragement be held out to this college to put itself upon a solid footing and to build up a strong medical institution.

"It is understood that the college officers have secured a building near the main building and will open a hospital where patients may receive treatment free of charge. A free dispensary is also to be opened in Lincoln, and by these additions the officers expect to satisfy the board that the law is being complied with."

Charity Hospital at Westchester, N. Y.—Although the Westchester Free Hospital has been open only a few days, hundreds of people have visited it, and each one has left a substantial donation. Each afternoon finds it surrounded with a collection of swell turnouts and delivery carts. Westchester has for the first time an institution on which people of all classes can unite, and a wave of charity has possession of the town.

The secretary, William Hesse Ballou, announces the following medical board for the hospital year: Consulting

physicians, Dr. Clement Cleveland, gynecologist; Dr. J. E. Ellis, Dr. Frank W. Jackson and Dr. W. B. James; consulting surgeons, Dr. Joseph W. Bissell, Dr. Arnold Naudain and Dr. Z. E. Lewis; out-patient department, Dr. W. C. Deming, Dr. Frank Anson Becker and Dr. W. B. MacNichol; pathologist, Dr. J. S. Thatcher.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from September 9, 1893, to September 16, 1893.

Major DAVID L. HESTINGTON, Surgeon U. S. A., is granted leave of absence for one month.

Lieut. Col. CHARLES R. GREENLEAF, deputy Surgeon General U. S. A., is granted leave of absence for two months, to take effect from August 25, 1893.

Capt. LOUIS A. LA GARDE, Asst. Surgeon, will, upon the completion of his duties in connection with the World's Columbian Exposition, report in person to the commanding general, Dept. of the Colorado, Denver, Col., for duty as attending surgeon and examiner of recruits at that city.

Lieut. Col. J. V. D. MIDDLETON, deputy Surgeon General U. S. A., is hereby granted leave of absence for one month, to take effect on or about October 1, 1893, with permission to apply for an extension of fifteen days.

First Lieut. CHAMBERLAIN, McCULLOCH, JR., Asst. Surgeon, is relieved from duty at Ft. San Houston, Tex., and ordered to Ft. Ringgold, Tex., for duty, relieving Capt. JAMES E. PILCHER, Asst. Surgeon. Capt. PILCHER, upon being relieved, ordered to Ft. Niagara, N. Y., for duty, relieving Capt. REuben L. ROBERTSON, Asst. Surgeon. Capt. ROBERTSON, upon being relieved, ordered to Ft. Omaha, Neb., for duty.

Col. J. C. BAILEY, Asst. Surgeon General, is granted leave of absence for one month, to take effect about the 3d instant.

Major CHARLES L. HELLMANN, Surgeon (Ft. Douglas, Utah), is granted leave of absence for one month, to take effect between the 25th instant and the 5th proximo.

Major J. VAN R. B. HUNT, Surgeon U. S. A., is hereby granted leave of absence for one month.

First Lieut. HENRY R. STILES, Asst. Surgeon, is relieved from duty at Ft. Omaha, Neb., and will report in person to the commanding officer, Ft. Meade, S. D., for duty at that post.

Capt. CHARLES E. WOODBRIDGE, Asst. Surgeon, leave of absence granted is extended four months, by direction of the Secretary of War.

Capt. JAMES L. POWELL, Asst. Surgeon, leave of absence granted is extended ten days.

There are six vacancies in the Medical Corps of the Navy.

The Marine Hospital at Port Townsend was partially destroyed by fire on the 9th, at a loss of \$3,500. The patients were removed to temporary quarters, pending the construction of a new building.

Marine Hospital Service.—The importance of the work done by the Marine Hospital Service in keeping watch for cholera in Europe during this season has been undeniably great. The latest reports received from its agents indicate that there is a good deal of the disease still on the continent in various places, while strenuous efforts are being put forth by the officials to conceal the facts. Plainly this is no time for relaxation of efforts on the part of our quarantine and sanitary officers. We have practically escaped cholera thus far, and we have learned much of value from last year's experience. But increasing vigilance alone can give us the assurance of continued safety.—N. Y. Tribune.

No. 14.

ORIGINAL ARTICLES.

AMERICAN INEBRIATE ASYLUMS.

Read before the Section of Neurology and Medical Jurisprudence at the Forty-fourth Annual Meeting of the American Medical Association.

BY T. D. CROTHERS, M. D.

SUPERINTENDENT WALNUT LODGE HOSPITAL, ETC., ETC.
HARTFORD, CONN.

Institutional care and treatment of inebriates began first in this country, and up to this time has attained a degree of development and prominence greater than that of any other country of the world. There are in Great Britain over forty asylums where inebriates are received and treated; and at least ten or twelve more in Europe; three are in India, two in Australia and New Zealand, and two opium hospitals are in operation in China. With the asylums in this country, the number will reach to about one hundred and twenty in the world. It is difficult to ascertain the exact number for the reason that many of these asylums are irregular in their work, and are associated with reformatories, sanatoriums and homes for mental diseases.

In Europe they are often sectarian church homes, and in this country many are private enterprises, dependent on the caprice of the managers and their successes. This is incident to every new work; and the formative stage, or the period of credulity that is always followed by the age of reason.

Asylum care of inebriates implies a recognition of disease and curability, which has been mentioned and urged for over two thousand years of the world's history. From the time of Hippocrates (and even before), down to the beginning of this century, the idea of drink madness and drink excesses being a disease, and curable by physical means, with restraint, has appeared in the science and literature of every age. Dr. Rush's writings in 1790 and 1809, seemed to have formulated the vague ideas along this line; although several European authorities carried the subject farther on they were practically unknown in this country; hence Dr. Rush may be said to have given the first inspiration and practical direction to the doctrine of the disease and its curability.

This idea was repeated in various ways, over and over again, until finally in 1846, Dr. J. E. Turner appeared as the first pioneer to build an asylum and demonstrate this fact.

Although the disease of inebriety had been recognized by a large number of eminent men in both this country and Europe, and asylums for their cure had been urged by the Connecticut State Medical Society of 1830, and the English Lunacy Commission of 1844, and others, the opposition of moralists and clerical reformers was so bitter and intense as to prevent any practical work. This has continued up to the present, only growing less and less.

In the year 1846, Dr. J. E. Turner of Bath, Maine, a practicing physician, became interested in the need of an asylum, from an ineffectual effort to save an early friend who was an inebriate.

He recognized the nature of the disease of inebriety and the need of hospital treatment and began an enthusiastic agitation of the subject.

He began by petitions and solicitations for money and influence to build an asylum, appealing to the New York State Legislature for years before a more recognition was given. So intense was the opposition that clergymen denounced it from the pulpit, and many of the religious and secular papers condemned the theory of disease and idea of an asylum as insane and opposed by all common sense and judgment.

At this distance, this period of denial and persecution appears like a glimpse of the dark ages, and the medieval spirit that opposed every new truth of science.

Finally, after ten years of persistent effort, despite the most bitter opposition he succeeded in forming a company to build an inebriate hospital, with the late famous surgeon, Dr. Valentine Mott, as president.

In May 15, 1854, the first inebriate asylum in the world was chartered by the New York State Legislature. Laws were passed giving power to hold inmates and charter was granted. The city of Binghamton bought a farm of nearly 200 acres of land and gave it to this company. Donations of lumber, stone and all kinds of building material were made on solicitation. The corner stone was laid in 1858, of what was later a magnificent building, and at one time the finest type of castellated Gothic architecture in the world. Six years later a part of the building was completed and opened for patients.

The founder, Dr. Turner, was a man of indomitable perseverance and tireless energy, who worked on without aid from others, begging money and material and superintending the construction of all the details of the building. At length in 1864, this first asylum of the world was opened for the physical care and treatment of inebriates at Binghamton, N. Y. The principles of treatment on which it was established were simply remarkable in clear, defined, scientific conceptions of the nature and requirements of such cases. Absolute restraint and control was provided, and no one was received for less than one year. It asked no pledges or promises from the patient; it aimed to give each one positive protection and medical treatment. The patients were locked in at night and only allowed out for exercise under the strict care of attendants. Turkish baths were given twice a week; work rooms were provided for those of mechanical tastes. Amusements of base ball, billiards, bowling and carriage drives were urged each day. Each case was considered a suicidal case

of insanity, requiring long medical care and restraint. No question of honor, or appeals to the pride was considered, but in all, the use of exact means and measures were carried out with military exactness.

These methods of treatment were far in advance of that time, and even to-day are just beginning to be recognized as the latest teachings of science. The principles, plan of organization, and treatment, although endorsed and supported by its distinguished presidents, Drs. Valentine Mott and John W. Francis, of New York, and Chancellor Walworth of Saratoga, created much difference of opinion and opposition. The patients themselves, after the immediate recovery from the effects of spirits, protested against the confinement and doctrine of disease, and sought in every way through their friends to break up the methods of treatment. As many of them had been influential men, and had prominent friends, a storm of the most bitter opposition began against the founder. Two separate views or theories of treatment became the center of intense feeling. The asylum and management insisted that each case was more or less diseased and should be under absolute control and restraint for long enough time to effect a permanent cure. The patients and their friends insisted that while the case might be diseased, his recovery depended largely on his liberty and promise to get well. That restraint was an irritation and an injury, also that appeals to his honor and manhood were the real agents for final cure. The founder and his friends insisted on long, absolute restraint and military control of the case, with the application of means and measures above all caprice and emotional changes of the patient. The opposition urged that restraint should be only nominal at first, and length of treatment vary with the man and his disposition, to which should be added moral appeals and moral remedies.

After a long, bitter struggle, the board of management changed and adopted a practically free and easy plan of treatment and Dr. Turner and his friends were turned out. The central object was to make the asylum popular with the patient. This unfortunate controversy gave new impetus to the moralists, and those who doubted the disease theory, and they joined in a wild crusade to show the folly of such institutions. The bitter controversy which gathered about the management of this asylum attracted the politicians, and the noted William M. Tweed of New York City, and others became directors.

All this time the asylum was crowded with patients, and the income was diverted to secure personal ends. Finally in 1867 the board of management deeded the property to the State of New York for one dollar, without the advice or consent of any one. From that time a series of misfortunes followed, during which seven superintendents were in charge in eleven years. Then the State changed the asylum to an insane hospital, and a political governor, in justification of the act, called the inebriate asylum a failure. Notwithstanding the conflicts of public opinion, and the changing methods of treatment by inexperienced men in charge, large numbers of persons went away permanently cured, as was clearly shown by statistics gathered the last years of its existence as an inebriate asylum. The enthusiasm which had centered about this work at different times faded, and the idea of failure and condemnation of asylum treatment for inebriates was spread far and near.

Had the physical treatment of the inebriate been a theory, this would have been its final death. But, like all other great enterprises of the world, the death of Binghamton Asylum marked the birth of a large number of similar asylums, some of which are doing grand work in the world. The great fact that inebriates were diseased, requiring positive hospital care, was demonstrated to the world by Binghamton Asylum beyond all question.

The advent of Binghamton Asylum was felt all over the world; even in far away Australia, an asylum was opened in 1859 that is still in existence. In Europe many small asylums began, although opposed as bitterly as in this country; yet they soon came under church control and gave great prominence to the moral and ethical side, and thus escaped the criticism others received. Long before Binghamton Asylum disappeared, a number of embryo institutions came into existence, many of which died from weakness and inability to bear the shock of opposition. Others struggled and are living to-day. One of these early asylums was the Washington Home of Boston, which began in 1857 as an inebriate lodging-house in the center of the city of Boston.

After years of opposition and serious trials it came under full medical management as a scientific hospital, and is now the oldest asylum in the world. Its late superintendent, Dr. Day, has had the largest experience in the management and cure of these cases of any person living. This hospital has had its wild storms of criticism and persecution incident to every new advance of science, but now receives about four hundred patients yearly. The second large asylum in the world that began in those early days and is doing good work, is Kings County Inebriate Home, of Brooklyn, N.Y., Dr. Blanchard, superintendent. This was opened in 1867, and, from small beginnings, has gone on to be a magnificent hospital crowded with patients. The disease of inebriety and the need of positive restraint and medical cure are the cardinal points of its management.

The Chicago Washingtonian Home was opened in 1867, and has been in successful operation up to the present.

The Franklin Home of Philadelphia, Pa., was opened in 1872, and is receiving a large number of cases every year.

The Walnut Lodge Hospital at Hartford, Conn., was opened in 1878 as a private corporate asylum, and has become prominent, although smaller than the rest.

These five are the largest hospitals in the world for the treatment of the inebriate. Over a thousand patients are received and treated yearly at these institutions.

The Washingtonian Home of Boston; the Kings County Asylum of Brooklyn, N. Y.; and Walnut Lodge at Hartford, Conn., regard the inebriate as diseased, and treat such cases on broad scientific principles.

The Chicago Home and the Philadelphia Home and some other asylums believe in the prayer pledge and moral influences as the most valuable of all means and remedies. Also that a short residence in the hospital is better than long treatment. Medicines are only used for temporary purposes.

These two classes of asylums represent the same old battle which greeted the first asylum at Binghamton, only less violent. The question of vice

and disease, as a compromise of half vice and half disease, is still the center of controversy. The first three asylums and a rapidly increasing number of small private homes and hospitals retain the principles and approximate to the plans of treatment laid down at Binghamton in 1864; while the others have no fixed scientific conceptions of the nature and needs of the inebriate or his malady.

Notwithstanding the misfortunes of the first hospital and its founder, a large number of similar places have been organized and managed with success.

As in all new enterprises, many of these hospitals must suffer from non-expert management and be organized on some theory of the nature and treatment of inebriety not founded on correct study and experience. After a time they are abandoned or changed to homes for nervous cases and insane. Over fifty different hospitals for inebriates have been established in America. More than thirty of this number are in successful operation; the others have changed into insane asylums, water cures, etc. Three large buildings or institutions are practically "faith cures," where all physical remedies and means are ignored. Several asylums are called homes for nervous people, to conceal the real cause, and thus protect the patients from the supposed stigma of inebriety. Others are literally lodging houses, where the inmates can remain a few days and recover from the effects of spirits. Several places make a specialty of opium cases; in some the treatment is empirical. In only a few of these hospitals is the disease of inebriety studied and treated on a scientific basis; the others are passing through the ordeal of "elimination and survival of the fittest" incident to every new advance of science. In many of the States large public hospitals are projected and awaiting pecuniary aid from the State or from other sources.

Of the forty asylums in operation in Great Britain to-day, only a very small number are conducted on scientific principles; the others are church homes and charitable retreats where temporary care is given for immediate necessities. A thorough scientific hospital has been doing grand work in Melbourne, Australia. Another has been organized in New Zealand under a competent board of medical men, and both of these hospitals are a credit to the skill and judgment of the managers. Two very well managed asylums are in operation in Germany and one in Switzerland. A number of similar hospitals have been projected in Norway, Sweden and France. In the latter country the inebriates are sent to insane asylums and placed in a ward by themselves. This has become an abuse which the superintendents of asylums have strongly denounced. The inebriate asylums of Europe are nearly all private institutions or under the control of churches and temperance societies. The Dalrymple Home, near London, is one of the largest and best equipped in Europe.

All these places, both at home and abroad, are yet in their infancy; not one of them are able to do the work that should be accomplished, because of the unjust criticism and obstacles which they have to overcome. The results of treatment in the few scientific hospitals for inebriates are most encouraging. The first statistical study was made at Binghamton Asylum in 1874. The object was to find out how many persons who had been under treatment continued temperate years after. Accordingly, 1,600 circular letters were addressed to friends of patients

who had been under treatment five years before, asking the present condition of the patient. The answers indicated 62½ per cent. as yet temperate and total abstainers. This result, after an interval of five years, was clear evidence that a large per cent. would, in all probability, remain cured during the remainder of life.

Dr. Day of Washingtonian Home, made a similar study of 3,000 cases who had been under treatment ten and more years before, and found over 32 per cent. yet sober and temperate.

Dr. Mason of Kings County Inebriate Home, examined 2,000 cases who had been away from the asylum for ten years, and found 34 per cent. of all cases yet cured. He expressed great surprise at this result, as most of the cases were considered incurable at the time of treatment. Other observers have made studies of a smaller number of cases with similar results.

The most careful authorities of this country and Europe agree in the statement that fully one-third of all cases who come under treatment for periods of three months or more are permanently restored. Other institutions where inebriety is treated as a vice, or by empirical methods, claim 80 and 90 per cent. of recoveries. It is needless to add that all such statements are not supported by published statistics. In view of the chronic character of these cases and the imperfect means of treatment, the results so far are encouraging, and indicate great possibilities in the future from a better knowledge and control of these cases.

Such is an outline view of the history and present condition of asylums in this country. The rampant empiricism which is so prominent to-day is indirectly rousing up a new interest in all asylums for inebriates. The increasing crowds of relapsed cases whose faith in the gold cure specifics has been misplaced, are rapidly filling up all asylums, and come in a measure prepared to accept physical treatment and to appreciate the need of means and remedies. There are ideals of the coming means and appliances essential for the successful treatment of inebriety towards which a few institutions are struggling. Each year's experience brings larger and clearer conceptions, and each institution is becoming more adapted for scientific work in this field.

An outline of the scientific treatment of inebriety in asylums in America will describe some part of the treatment common to each, but not yet attainable in its entirety, because of the numerous obstacles and want of support from public opinion and other conditions.

The situation of an asylum in the suburbs of a city or in the country near large centers, with ample grounds for retirement and quiet living, are essentials. A proper building, equipped with baths and all the appliances for comfort, with means of amusement, joined with ample legal power to hold the patient a year or more, are equally essential. They should be called hospitals, not only in full recognition of their physical disabilities, but as places where every condition of life can be regulated and every surrounding can be made to aid recovery and restrain. Literally a quarantine hospital, where isolation and removal of all the exciting causes, combined with appropriate treatment to build up and restore the deranged functional activities of the organism, can be obtained. The time of treatment should be from

six months to two years, and be governed by the condition of the patient and extend to a legal control on parole for a long time after leaving the asylum. In Connecticut the law gives control over all committed cases for three years, whether on parole or otherwise in the limits of the State.

The hospital should provide exact military restraint with duties and responsibilities, rewards and punishments suited to the condition and capacity of the case; also work, amusement and occupation, both mental and physical, as medicinal agents. Every condition of life should come under exact military control: baths, exercise, sleep, food and medicines all to be regulated and applied uniformly. Each one should be treated as suffering from profound disease of the brain and nervous system requiring long rest and building up. The general treatment should begin with an examination and inquiry of the facts concerning his past life and present condition. These examinations should be repeated every few weeks, because of the rapid changes and errors which are impossible to guard against in the first and later examinations. The use of spirits should generally be abandoned very early in the treatment, and the return of the drink paroxysm anticipated by the use of drugs, baths, exercise and special control.

Many of the paroxysmal drinkers are practically epileptics and require similar treatment. They are suffering from grave disturbances of the physical centers, and physical remedies are required in addition to other means. Other cases are delusional maniacs and paranoiacs out of harmony with every condition of natural, healthy living, and unable to correct and adjust themselves to such conditions. In others, nerve exhaustion is at the bottom of the drink impulse; inherited tendencies, reflex irritations, and many complex conditions which can only be discovered and treated in hospitals. When these are treated the causes are removed, and the alcoholic soil is exhausted and dies away.

States of poisoning from stupor to full delirium are made the subject of special treatment, according to the experience and theories of the physician. These acute symptoms followed by chronic conditions, require equally special remedies and means.

These are some of the general ideals in treatment to which every scientific asylum is moving. All asylums suffer for want of ample legal authority over their cases for sufficient time to secure permanent results. Public opinion regards asylums as of only temporary, and in most cases of doubtful value. The theories of their work are openly termed "fads," and supposed to be founded on some mercenary or selfish purpose. The pulpit, press and ultra reformers pass by on the other side, like the Levite. Public patronage is withheld, and most all asylums depend entirely on the income of patients for support. Hence they are more or less crippled in every way. Many asylums suffer from poor location, bad buildings and surroundings, inability to classify the inmates and apply special treatment to each one. In many places baths and systematic exercises cannot be secured. The nutritive, hygienic and passive treatment can not be carried out on the details of the managers; hence many asylums are using the means within their power in anticipation of looking forward for larger and more perfect facilities.

The treatment of inebriety not only includes

everything found valuable in hospitals for the insane, in reformatories of the most advanced type and in the modern sanitarium and homes for neurasthenics. The essentials for treatment in each of these classes are required for the inebriate. The asylum managed on the scientific plan of providing for the requirements of each case, must have the power of control, and special buildings the same as to the hospitals for the insane; the discipline and management of the modern reformatory and the appliances of the best sanitarians and private homes; then it can approximate to a measure of success in the treatment, that at present is only in outline. American asylums are leading the world in these directions of practical work, and while no one has combined only in the crudest way these appliances, many asylums are approaching it yearly. Asylums all over the world are at the beginning and infancy of their existence. A great deal of preparatory work must be done before they can reach the first stage of scientific work. The moral remedies by appeals to the will power and morals of the case must pass away. The delusions and palsy of the higher brain centers must be recognized, and dissolutions beginning in the ethical centers extending down to all the lower faculties must be studied. The great fog banks of metaphysical theories of free will, moral depravity, vice and wickedness, must disappear from all conceptions of inebriety, and its practical management in asylums. Asylums and managers who act on the theory that the inebriate is half wicked and half sick are crippled. Asylums and managers who attempt by drugs or moral appeals to restore and cure the victim are still far back in the stage of credulity. The specific vaunter, who professes to break up the symptom for drink as if it were the disease itself, is an empiric, either ignorant or by design. Asylums and managers who teach dogmatically the nature of inebriety and its only true remedies, are not very far along in their scientific work. Asylums who claim large percentages of cures from certain means and remedies are not worthy of confidence.

Inebriety is found, when carefully studied, to be the most complex neurosis of modern research, dependent on heredity and many physical causes, also physical condition and environment that are not clear to the most minute study. Asylums for treatment so far, by isolating the patient place him in the best condition for study of conditions and applying means for relief.

The more thorough this study, the wider the range of causes appear, together with the means and methods of relief. The most advanced asylum of to-day follows a general prospective plan of treatment, and has no specifics or no special theories that are not open to change and re-adjustment. Beside a few general facts, which stand out like mountain peaks in a new land, all the intervening space is unexplored. No one can speak dogmatically as to where inebriety begins and what the exact causes may be. No one can explain the varied phenomena of drink storms, of the action of spirits on the brain, of the power of heredity, of the brain condition which demands relief by the craving for narcotics, of the sudden cessation of this drink impulse under unusual circumstances, of its equally sudden outburst from causes unknown. Even in asylums the same uncertainty exists. Cases that

seem restored relapse, and others that are considered incurable become restored, showing that our present knowledge is very imperfect, and the known is comparatively nothing in contrast with the unknown.

Running through all this phenomena of inebriety is an outline of a uniform movement of cause and effect: of events following each other according to some law; good examples are the periodicities of the drink impulses, and the outbreak of such impulses from the presence of certain conditions that can be foreseen and studied. Patients under care in asylums present a remarkable uniformity of symptoms and progress that is often startling to the student. Not unfrequently such cases can be anticipated and the results of treatment known far in advance. The drink symptom is dependent on some conditions of brain degeneration and changes. It will suddenly die out and disappear under the most adverse conditions and surroundings. Examples are numerous of persons who become temperate, sign pledges, and stop all use of spirits under the most unfavorable circumstances. Every temperance and revival meeting furnishes illustrations of persons who are restored permanently, although the same means have been used many times before with no results.

Persons are known to stop drinking from the slightest supposed reasons, and in all these cases the last means used are credited with being the active causes. The true explanation in all these cases is that some change or evolution of brain function has occurred and the drink symptom has died out. It is not the last prayer pledge or solicitation of others, or the last drug or remedy of special means used that has caused this change. Other and more obscure causes are at work, and the time comes when their action is apparent in the cessation of the drink impulse. Physicians in charge of asylums recognize this fact, and realize that their best efforts are in building up the brain and nervous system, and placing the organism in the best possible condition for both organic and functional change. Remedies directed to the drink symptom are never curative; a dose of mercury acting on the liver is a rational method, more so than bromid to check the drink impulse.

Asylum study of these cases show that inebriety is often a symptom or phase of a neurosis which may break out and change to some other form. General paralysis, melancholy, and many forms of insanity, together with tuberculosis, and various neurotic affections follow frequently on the subsidence of the drink craze.

The statement that the gold cure specifics are followed by an increased number of insane among those who have used the treatment must be a literal fact. The proof of such a statement is found in the experience of every asylum, and the general principles of neurotic diseases. The number of such persons can not be easily determined, but the more powerful the narcotic used to stop the drink symptom, the more certain insanity and profound degenerations of the brain centers will follow.

All asylums for inebriates suffer from the large number of incurable inmates. Persons, who, after an uncertain course of treatment go away, relapse, and condemn the asylum for their failure. Much of the current opinions concerning asylums are formed by the irresponsible statements of incurables. Such persons seem to take pleasure in denouncing asy-

lums in every place, and castigating themselves and their inmates. On the other hand, persons who have received substantial benefit from their treatment, and their treatment and residence in an asylum. The result is that all institutions are judged by the unthinking public from the statements of those who have failed to receive any benefit from its work. Unthinking physicians who suppose that the control of the drink craze is the central object of treatment often lend their influence to unfavorable criticism of asylum work. This, joined with later condemnations of moralists, complicate and increase the difficulties of every practical asylum, trying to understand scientifically this new field of medicine.

American asylums have many advantages over all foreign institutions, in freedom of caste and prestige; also in ability to follow independent lines of work and rise above the prejudices and opposition of those who dread change and advance. Some general conclusions may be stated as follows:

1. The asylum cure and treatment of inebriates began first in this century, and has grown and extended to all civilized nations of the world.

2. American asylums have developed the disease theory and the practical character of physical treatment in institutions, beyond that of any others in this field.

3. Asylums in this country represent nearly all stages of development and early growth, from infancy and childhood, with its feeble conceptions and infantile efforts, to the boastful assumption and over confidence of youth, on to the dawning truth of early manhood when reason and judgment begin to reign.

4. A few of these asylums discern some great outline truths which may be stated with confidence as ideals towards which there is a rapid movement.

5. Inebriate hospitals must take the place of jails and station houses.

Such places are dangerous in their mental and physical surroundings by intensifying the degeneration and removing the patient beyond hope of recovery. They are in many cases literal training stations for mustering armies of chronic maniacs that never desert or leave the ranks until crushed out forever.

6. Inebriate hospitals should receive the incurable inebriates and make them self-supporting, and build them up physically and mentally.

They would relieve the taxpayer and relieve society of untold burdens of sorrow and misery.

7. Inebriate hospitals should receive the recent cases and place them in the highest conditions of enforced health and vigor, and thus return a large number to health and society again.

8. Inebriate hospitals can and should be self-supporting when once established. They should be managed on scientific business principles, like military training schools.

9. Inebriate hospitals should be built from money raised by taxes on the sale of spirits, on the principle that every business should be obliged to provide for accidents which grow out of it.

10. These are the realities which every inebriate hospital is approaching and which all experience points out as practical and literal in the near future.

11. The inebriate hospitals of today are only in the infancy of their work, contending with great opposition and prejudice, misunderstood, condemned, and working against innumerable obstacles.

12. Lastly, there is an intense personality in inebriate hospitals to each one of us.

They may bring salvation and restoration to some one near and dear.

They may be fountains of healing whose influence shall cross and influence our pathway in many ways.

13. Inebriate hospitals and their work are the great new lands which only a few settlers have reached. They are calling to us to come up and occupy, and thus help the race on in the great march from the lower to the higher.

Dr. J. K. KING, Watkin's Glen.—The essayist deserves great praise and credit for his long and patient work in this often unthankful line. The doctor stands eminent in this line of work. I have had opportunity to watch him very closely many years, and I consider him probably the best representative in this country on the view of inebriety being a disease. I do not know how many of us would go as far as he does in that line, but certainly he has done advanced work and has brought out that side. I have had a good deal of experience myself with these cases in various forms of treatment, and I seem to recognize in them two great elements: one is the element of disease which is a form of neurasthenia, and the other is the element of habit. I recognize habit as entering very largely into this thing, and there is no question but that habit after a time may become a disease. Now the methods of treatment lie in two lines: one is that of public inebriate asylums and the other of private institutions. The question is which is to take the advance. The public institutions are always subject to the danger that Buffalo and Binghamton have met; that is, getting under the influence of politics and following the unfortunate history of the asylum of which Dr. Dewey was the head. Private institutions lack one great quality of the public; that is, the ability to hold and retain the patient for a long time. The doctor has mentioned the length of time, and it seems to me from my experience that time is a great element in these cases. I have never found much difficulty in breaking up what you might call the disease. Turkish baths and other things, building up the system, etc., answer that purpose; but the difficulty is to retain them long enough, until the habit is broken off and until the moral character and the physical strength are established sufficiently for them to stand and let it alone. There lies the secret. When we can solve that question, we will have no difficulty in curing a great many; but the difficulty is to retain them long enough. Just as soon as a man who is accustomed to drinking gets fairly over it, his spirits rise at once and he thinks he is a free man and he is capable of going anywhere and having no trouble in the future, and he again rushes into temptation, and before he knows it is drinking. The fact is, the institutions do not retain the patients long enough to establish their physical and moral character. The doctor's idea of a State institution supported out of the funds that come from the sale of liquor is a very good one, but the question is, how long before it can be carried out? It reminds me of something that I saw when in Oklahoma last fall. In one of the principal streets in Oklahoma city there was a very large saloon where everybody seemed to go, and right overhead was a Keeley cure, so they went right together; they got finished up downstairs and went upstairs to recover. So I am afraid it will be in this question of establishing asylums out of the money that is received from the sale of liquor.

Dr. J. G. KIERNAN.—The history given by Dr. Crothers is exceedingly interesting, and he mentioned some matters which were not worthy in regard to the New York experience. He did not, however, call attention to one of the most peculiar performances under Tweed and the régime, which

was the attempt to reform an inebriate physician by placing him at the head of the inebriate asylum of Binghamton, the gentleman being imported for that purpose from Chicago. I may say here that the Washingtonian Home in Chicago is a theme of ridicule. It is notoriously only a sobering up place, but so delightfully conducted that little arrangements of this kind crop up now and again; the inmates go off on a spree and their absence is first discovered in the police station. No attempt is made at treatment, except a certain amount of moral suasion and the medical agency of the miraculous pre-Raphaelistic chart which the head of the institution has hanging on the wall, and which he descants on to the admiration of the inebriates.

Dr. Crothers ignored one fact, i. e., that between 1864 and 1882 there existed what may be very well called the Philistine era of American psychiatry. That was the era when every bit of insanity was crammed into a very short Procrustean bed, and medical societies seemed the mouthpieces of mobs to enunciate certain lynch law doctrine with regard to the insane. It seems to me not a few of those blind sprees resemble in a great many of their characteristics the period of stupidity that occurs in many epileptics. The reference to certain cases healed by prayer, etc., brings into consideration another element the doctor did not take into account. Every one knows that under certain conditions, while the subject is not hypnotized, he is in a peculiar state of mind and peculiarly liable to suggestion. That suggestion, that conception, coming under those conditions, dominate the man when nothing else will. With regard to the legal status of the question, it is the same as with the criminal. The inebriate can not be properly taken care of any more than the habitual criminal, until he is regarded on the same level as the insane. Under our law in Illinois there is one very curious anomaly. The inebriate is not for custodial purposes an insane person, while civilly he is, because when a man becomes an habitual drunkard you have a guardian appointed just the same as over an insane person or minor. In other words, the disease theory, and it can be regarded as nothing else, is taken into account in what might be called the civil aspect of the subject, but in what might be called the criminal aspect it is totally ignored.

Dr. CLARK GAXEN, Omaha, Neb.—I would like to say a word in regard to the suggestion of police control in these cases. I am fully and heartily in accord with the doctor that this subject should be regarded and treated as a neurosis. I think I can go as far as any one in the acceptance of that theory. In my mind it is simply a vaso-motor neurosis usually induced by long continued use of alcoholics, but sometimes the neurosis occurs without such influences, and seems simply to spring up; but I think that especially should there be a different control in cases of this kind from ordinary police cases. Washington is the only city in the country that has adopted that police control. The superintendent of police there takes this view of it, and has arranged and equipped his department with reference to the management of those cases outside of the police station. He does not take those cases to the police station unless it is absolutely necessary and the individual has no other place to control him temporarily. As to the view that Dr. Kiernan has just expressed, I think that is simply deficiency in the law; the law is simply behind science in that respect. Chronic inebriety, that is this special form of temporary insanity, should for all purposes of control be regarded entirely as other forms of insanity are.

Dr. J. E. EMERSON.—I have one criticism to make. It seems to me the doctor is in error in saying that there is such a disease as the drink disease. I think it would be much more correct, judging from my own observation, to say that the tendency to drink arises from a variety of morbid condi-

tions, of conditions of imperfect development, which manifest themselves in some form of tendency towards indulgence in narcotics, not necessarily a disease, but resulting from various conditions. I do not think we can yet say that there is a disease. One man has spasmodic paroxysms of drink, another man simply has a feeble will and falling in with boon companions, gets to drinking. I think they should be classed as an entirely different condition. Still I think we must all agree that there is a physical basis, either in imperfect development, or you may say in a condition of partial degeneration of the general nervous system, lowered tone, at least a physical basis.

As regards the possibility of restraint which has been spoken of, our laws in Michigan provide for it, but in a very peculiar way. They provide for the appointment of a guardian on the application of any near relative, any blood relative or husband or wife; this guardian under the order of the judge of the probate court may send such patients to any hospital, asylum or sanitarium for treatment, to be retained there at the option of the guardian, with the proviso that the guardian must make a report whenever called upon by the judge of probate who sends the case, or at stated intervals of six months. I have in very many instances endeavored to get friends to place their relatives under the provisions of this law, but have never yet succeeded, although I have recommended it in many instances. The judge of probate has been invoked and has simply said he could not carry out the provisions of the law. Why, I never could find out.

DR. JOHN G. REED—I have been very greatly interested in Dr. Crothers' paper and almost as much so with the comments upon it. For some time I have been giving some extra attention to this department of neurology, and it is very singular how one changes his mind as he comes in contact with men. I, at first, under perhaps the influence of enthusiasm, supposed that I had established some principles that would be abiding, and when I came to test them by the opinions of others, I was disposed to change them a good deal. It reminds me a good deal of the saying that the friend of to-day is the enemy of to-morrow and the enemy of to-day is the friend of to-morrow. It brings up the idea that this department of neurology is in a formative stage and that we hardly have any well defined principles of general application except in theory and those not well tested by clinical data. The gentleman on my right, taking exception to saying that we have the drink habit disease, or that the drink habit should be called a disease, seems to me to be somewhat in error. I hardly know how you will avoid using the term in the investigation of so broad and deep a subject. It seems to me that the multiple conditions are those of constitutional or congenital deficiency, which finally blooms out in inebriety, and that this should as much be called a disease as those conditions which produce epilepsy and other classified neurotic conditions.

DR. W. H. WELLS, Marshfield, Wis.—The paper just read is very interesting and very important to us all, and there are two views that might be taken of the neurosis side of the question, as to whether the neurosis is primary in the majority of cases, or whether it is acquired. Now I think there are two classes that we have; one in which the neurosis is primary and a still larger class in which it is acquired from the constant habit of drinking. As one of the members, in advocating the neurosis and sanctioning that view said, in the majority of cases it is brought on by the habit of drinking. I think it is well established that this habit of drinking can be acquired, and the constant habit then does produce a neurosis. The habit of drinking we can acquire the same as we can acquire habits of eating. We can acquire a taste for articles of food that when we first begin to eat are

very disgusting, and it seems to me that in the majority of cases the habit and the neurosis are acquired rather than that it is a primary neurosis. You take the child born of drunken parents and the disease may be direct, primary and hereditary, while another boy may start out being healthy in all respects and thrown in the company of drunkards and the habit gradually fixed upon him, although he begins in a perfectly normal way and having no desire for it; but the desire is acquired and finally produces a neurosis that perhaps would require constant treatment in order to cure.

DR. WILLIAM THOMAS BISHOP, Harrisburg, Pa.—I began to be a temperance reformer on the reform idea. After a while I came to the good, sound, sensible idea that drunkenness was a form of insanity as much as horse-stealing or any other similar disease, and I think the mistake that they make is simply trying to get away from the fact and trying to make a compromise. I think that there is where the whole foundation is and the nearer you get back to it as medical men and recognize it as a fair and square issue, that it is a disease and that it is a form of insanity, that the law which governs it is the same as any other phase of insanity and the restraint the same, the nearer you will come to accomplishing what you want. Another thing; drop this indiscriminate use of the words, asylum and hospital. I have a great deal of fault to find with our brother about that; he straddled from one side to the other; an asylum might be a place for those that are chronic. Our State of Pennsylvania is just building an institution for the chronic insane; that would be an asylum; but as long as there is any hope, as long as this disease can be treated with a likelihood of cure then the term should be hospital. I think the idea of having the hospitals or asylums supported from the revenue from intemperance is all nonsense. Make the State realize the responsibility they have for the protection of these people and the protection of society. There is no question but that some people are natural perverts just as much as they are natural horse thieves, while others acquire it. One thing must be kept in mind; that is, the continued use of alcohol or any other stimulant will cause an absolute breaking down of the tissue just as much as the injury of a hand in coupling on the railroad or any other injury; it is a permanent thing and you can not get away from that. You can only restore them the part that is left; you can not re-create, and the quicker we realize that it is a form of insanity and needs the same restraint and needs the same obligation on the part of the State for the same support, the nearer we will be to accomplishing what we need. Take a man insane on any other subject and try to develop in him a certain degree of moral responsibility. I went not long ago to a church service in an insane hospital; there were several hundred there. An epileptic was seized with an attack and wanted to fight and there was an old soldier next to him who had been in the English army who became very enthusiastic and did not want to see this friend of his abused. I said to him, You would not fight an old soldier, would you? and he quieted right down. That will work, but you must remember that it is a disease and that the other is only an incident.

DR. T. D. CROTHERS—I am glad to note such a general interest in a topic practically unknown. You may theorize for a long time and not get at practical facts. However, I will say that disease seems to be the only word that will explain the phenomena which appear in all these cases, although it is to be deplored that we insertibly associate these vague terms, such as habit, vice and free-will in the most indefinite way with these cases. More error confessed adds intensely to the disorder. This is a new phase of neurasthenic disease that will have a very large future and we can only be investigators. We should not theorize and think by so doing we have accomplished the highest good in this field.

SARCOMA OF THE PIA AND BRAIN, SIMULATING BRAIN TUMOR; MONO-SPASM AND MONO-PARESIS; OPERATION: DEATH ON THE THIRD DAY.

Read by title before the Section of Neurology and Medical Jurisprudence at the Forty-fourth Annual Meeting of the American Medical Association.

BY J. T. ESKRIDGE, M. D.
DENVER, COLO.

E. T. P., male, aet. 50, Iowa merchant, was referred to me by Dr. W. J. Rothwell. His family history is excellent. His health during childhood was good, with the exception of headache, from which he suffered considerably during attendance at school. After he left school his headache ceased almost entirely. He denies more than occasional use of alcohol, or excess in venery. During his twenty-first year he contracted a hard chancre and a few months later he lost most of the hair on his head. There were no other secondaries. About seven years after the initial lesion of syphilis he married. His wife lived nineteen years, and during this time she had several miscarriages, none of the children reaching full fetal development. The wife died a few years ago with brain trouble (probably syphilitic). Mr. P. seemed to continue in first-rate health until the summer of 1889, when he began to suffer from uncomfortable feelings in the back of the head. These sensations at first did not amount to pain, but as time went on he had occasional attacks of headache. Two years after the first appearance of the head symptoms, or early in the morning of July 8, 1891, while he was feeling quite well, without any aura, he was seized with a general convulsion which lasted three or four hours. He remained in an unconscious condition four days. The attack was not immediately preceded or followed by headache. During the next two months he felt nervous, his face was flushed, and he became sleepless, languid and lost flesh. He did not suffer with a distinct head pain, but he experienced an apprehensive and confused feeling.

In September, 1891, he experienced a seizure, during which he did not entirely lose consciousness. The attack began by a sensation which he likens to the imaginary feelings caused by one inhaling some deadly poisonous gas with a vague, indescribable taste. There was no distinct odor or taste. Immediately following these sensations he felt a nauseated sensation at the stomach, and a peculiarly indescribable sick feeling in throat. There was an increased flow of saliva, slight drawing of the face to the left, and he seemed to himself dazed.

From October, 1891, till the time of his first visit to me (June 30, 1892), there has not been a day during which he has not experienced one or more of what he calls "nervous discharges." The attacks are said to be similar in character. They have all been attended by a profuse flow of saliva.

He has just had an attack in my office.

He shakes all over, as if suffering from a violent chill, turns pale and moans. There is slight twitching of the muscles of the left side of the face, increased flow of saliva on left side, the left thumb is drawn down into the palm of the hand, with slight flexor contraction of the fingers of the hand. There is a loss of consciousness. Immediately after the attack, which lasts only a minute or two, there is paresis of the left hand, wrist and face muscles, with

slight ptosis and wrist drop. Left pupil widely dilated. He describes his sensations as oppressive breathing, a sick feeling in throat, with intense chilliness, a peculiar taste, which he describes as an "electric taste." On questioning him further to ascertain if the sick feeling is not experienced in stomach instead of throat, he affirms that the sick sensation is in throat and left side of face. He says at times he feels as if the entire left side of body were on fire.

Examination, July 1, 1892.—Gait is somewhat halting, the left leg being used more awkwardly than the right. On closing eyes and walking backwards and forwards the disparity between the legs is more marked. There are no distinct ataxic movements of legs, trunk or arm muscles. Right leg muscles are much stronger than the left. Dynamometer: R. 150; L. 142. Knee jerks: R. nearly normal; L. sluggish, but variable, and increased by reinforcing. Deep reflexes of arms, increased, and nearly equal in each arm. Plantar reflexes, absent on both sides, although stroking the plantar surfaces causes some contraction of the leg muscles. Cremaster reflexes, present and about equal. Lower abdominal and epigastric reflexes, absent. The abdomen is very large, and covered with a thick layer of adipose tissue. He has double inguinal hernia. All sensory phenomena normal on right side. On the left side all sensory phenomena blunted, but not abolished except in parts to be noted. In left leg temperature sense is most affected. Cool substances are readily recognized as such, but warm substances make no impression as such until they have been in contact with the limb a few seconds, and then the impression is much less distinct than that made by the same substances in contact with right leg. Touch, pressure, posture and localizing senses seem to be slightly lessened in right leg. Pain sense is normal, or nearly so. On the trunk, little or no difference is recognized in the sensory phenomena of the two sides. On the index of the little finger of left hand he is scarcely able to recognize two substances as such even when held three times the normal distance apart. In other portions of the left hand, in left arm and face, there is only slight blunting of the sensory phenomena, less than is found in the left leg. Smell, normal. Taste, nearly normal, except on the left side, just immediately after an attack, when it is temporarily, nearly lost. Hearing: R. 1-12; L. 1-12. Tuning fork is heard about equally distinct in each ear.

Eyes: R. v. 20-40. All fields slightly narrowed. Pupil normal in size, and reacts to light and accommodation. Some whitish atrophy of optic nerve. Arteries nearly normal in size, veins full and slightly tortuous. L. v. 20-200. Yesterday just after one of his attacks, the pupil was dilated to three times the size of the right, and it did not react to light or accommodation. To-day the pupil is normal in size, and reacts well to accommodation, but slowly to light. Fields all lessened; temporal absent. Nerve very white, and shows distinct atrophy. Some drooping of upper lid.

He is ordered ten grains of potassium iodid thrice daily, and the dose to be increased five grains each day.

July 3, the medicine has not been given regularly. On the night of the fourth, he has a convulsive seizure, beginning in the left side of the face and extending throughout entire left side of the body and limbs, and three attacks of like character on the night of the fifth. During these seizures he is unconscious. July 6, he is taking thirty grains of potassium iodid thrice daily, and one-sixteenth of a grain of the bichlorid of mercury is given with each dose of the potassium. At 6 p. m. I find his face of a purplish color, he is very weak, and left side of face paralyzed. Dyn.: R. 120; L. 37. Saliva is constantly flowing in great quantities. Speech is thick, but he has no aphasia. Memory very poor. During the day he has had several convulsive seizures limited to the left side of the face, but consciousness has not been lost. On the seventh and eighth he has had three or four convulsive seizures in left side of

face, but no disturbance of consciousness. Immediately after an attack speech is impossible, and the muscles of the entire left side of the face are paralyzed and remain so for some time after the muscular twitching ceases. The aura preceding the attacks are electric shock-like sensation in left side of face, with a flat or stale sense of taste, and great burning in left side of face. On the ninth he has several somewhat similar attacks, one of which I witness, and it may thus be described: he shakes himself as if feeling chilly, complains of an intense and disagreeable cold sensation running up the upper portion of spine, and almost immediately the muscles of left side of face began to twitch. The left masseter seems to be the first muscle affected, then the left eye becomes convulsively closed and opened, followed by tonic closure of the eye; left side of forehead is next corrugated and drawn to left; mouth is now drawn well to left with clonic twitching of the muscles, and immediately following this, the left masseter and platysma myoides muscles begin a series of clonic convulsive movements which are kept up several minutes. Finally the left trapezius and left posterior neck muscles become tonically contracted and draw the head backward and to the left. The sterno-cleido-mastoid muscle does not seem to be affected. The left masseter and platysma muscles keep up a clonic contraction several minutes after all the other muscles cease to be affected. Within a minute after the convulsive movements begin, the left hand drops, and the left wrist and hand muscles are completely paralyzed. I ask him to raise his right hand and arm. He does this without hesitation, but is unable to move the left hand. The paralysis of the wrist and hand passes off before the platysma and masseter muscles cease to twitch. During the attack there seems to be some spasmodic action of the muscles of the pharynx and larynx, most marked on left side, but affecting the muscles of the right side to some extent. At the height of the seizure the right masseter muscle occasionally twitches. The seizure lasts about ten minutes and during this time he is unable to open his mouth. After the attack the muscles of the left side of the face are completely paralyzed and flaccid, and remain so for several minutes. This side of the face is paretic between the seizures. He remains speechless for several minutes. When he is able to talk, he tells me that "at the commencement of the attack he experiences an electric shock, which seems to shoot through the entire left side, including arm, trunk and leg as well as the face."

July 10. He is now taking seventy grains of potassium iodid thrice daily, and has had three attacks similar to the one described, but he thinks they are less severe.

July 18. He is now taking 110 grains of potassium iodid thrice daily, and has experienced no convulsive movements for three or four days, although he still has chilly sensations in back of neck three or four times daily. Vision has greatly improved. Right eye, $v-\frac{1}{2}$, with nearly normal fields; L. $v-\frac{3}{4}$. All fields except temporal, which is lost nearly up to median line, nearly normal.

Aug. 1. No convulsive movements of any muscles since July 15, but he experiences what he calls "explosive cold spells" two or three times each day. The cold sensation, which he says is intense, begins in left cheek, and spreads over left side of face,

down spine and over left side of body. There is constant tremor of the left depressor anguli oris. During last two days he has had headache for an hour each day.

Sept. 1. Only slight change in symptoms since last record. It has now been six weeks since he has had any convulsive movements. The tremor in the left depressor anguli oris still continues. About two or three times each day he has a "deathly" sick sensation arising from stomach, and almost instantly he experiences a cold or freezing feeling, which begins in left side of face and passes down left side of trunk. He is now taking 125 grains of potassium iodid and one-twelfth of a grain of corrosive sublimate thrice daily, and seems to have but little inconvenience from these agents. He has gained considerably in flesh.

The diagnosis is tumor in the lower Rolandic region, and an operation has been discussed, but owing to the probable syphilitic nature of the lesion it is discouraged in favor of continuing the anti-syphilitic treatment. General sensibility, including tactile, temperature, pain, muscular, posture and localization senses, normal.

Early in September (1892), he becomes mentally greatly depressed; is apprehensive and says that he is losing his memory. There is no decided headache, but a dull, confused sensation in the head is constant. There are no convulsive seizures, but he still experiences the "cold sensations." He now becomes urgent for a surgical operation, and says that he would rather be dead than endure the mental suffering that he has to undergo. He fears, if something is not done to relieve him, that he will commit suicide. After explaining to him the unsatisfactory results following operations for the removal of syphilitic growths of the brain, owing to the tendency of the disease to involve adjacent portions of the brain and membranes, he decides to take the risk, saying if he could not get relief he is determined to die. The entire left side of face still remains paretic.

On Sept. 10, 1892, Dr. Parkhill, after employing thorough aseptic measures, makes a trephine opening in the skull one and a half inches in diameter, with the center of the trephine over the lower extremity of the fissure of Rolando. The bone is quite thick and very hard. On exposing the dura its external surface seems normal. There is undue tension of the membranes and no pulsation is discovered. On applying the poles of a faradic battery over the exposed membrane no contraction occurs in any muscle. The dura is opened and considerable watery fluid escapes. Feeble pulsation of the brain is now observed. The pia is opaque and greatly thickened, so that the convolutions of the brain can not be seen through it. Portions of the pia are from one-quarter to one-third of an inch in thickness. On applying the Keen double-electrode, attached to a Flemming faradic battery, to the exposed brain substance, and using a current sufficiently strong to produce smart muscular contraction when applied to the hands, no muscular contraction takes place. The trephine opening is enlarged in all directions, and the same opaque and thickened condition of the pia is observed. A small incision is made into the brain substance, but nothing abnormal is found except brain substance is darker and firmer than normal.

With the thickened condition of the pia it is thought best not to explore the brain farther.

The patient stands the operation fairly well. The parts are dressed antiseptically and he is placed in bed, carefully surrounded by warm bottles.

Before the operation he made me promise that I would not let him suffer much pain after the operation, and that he should have sufficient morphin to make death painless should his case prove incurable. The operation was finished about 1 P. M. He sleeps until 5 P. M., when he awakes and complains of agonizing pain in the head. He is given one-quarter of a grain of morphin hypodermically. The same dose has to be repeated once or twice during the night, as he insists that his suffering is unbearable. The day after the operation his pulse, which had been about 100, increases to 120, his temperature arises to 101 degrees, and he is restless and complains a great deal of pain in the head. He refuses food, and it becomes necessary to force nourishment upon him. Two or three hypodermic injections of morphin, one-quarter of a grain each, are necessary to quiet him during day. On the morning of the second day after the operation he is evidently failing rapidly. During the night he has had several convulsions limited to the left side of the face, and one which involved the whole of the left side of body. As the forenoon wears on he sinks into a stupor, and by the afternoon he is profoundly comatose. He died quietly at 6 P. M., about fifty-three hours after the operation.

Section cadaveris, three hours after death. The brain only was examined. On removing the dressing the wound was found to be free from pus, and no evidence of inflammation was present. The dura was not abnormally adherent to the skull cap. The veins and sinuses of the dura were distended with fluid blood, but the external and internal surfaces of this membrane presented no macroscopic pathological changes. On removing the dura, the pia over the greater portion of the right frontal lobe, over the right Rolandic region and over the right temporo-sphenoidal lobe laterally, appeared opaque and thickened. The greatest thickening of the pia was over the lower Rolandic region, where it was at least one-quarter of an inch in thickness. The pia, over the entire surface where it was opaque and thickened, was abnormally adherent to the brain substance, and in some places, in endeavoring to detach the pia from the brain, portions of the cortex came off with the membrane. On carefully sectioning the brain no gross lesions were found, except in the lower Rolandic region, especially in the lower face center, where the cortical substance seemed abnormally dark. The incision into the brain substance, made during the operation, was found to be in the lower portion of the ascending frontal convolution, on a level with the lower end of the fissure of Rolando. Portions of the thickened pia and of the cortical substance of the brain, immediately beneath this membrane where pathological change seemed the greatest, were hardened in Müller's fluid for three months.

Microscopical Appearances.—Pial membrane thickened, in places fully an eighth of an inch (one-fourth to one-third inch in fresh state).

"This thickening is due to small round cells in a delicate gliomatous tissue. Blood vessel walls thickened, intima thicker than normal, complete occlusion of some vessels. The tissue takes the stain very readily.

Diagnosis.—Sarcoma (small round-celled). Glioma tumor mass in membrane.

"Sections show a delicate capsule of connective tissue, covered by endothelial cells. From the capsule delicate

hands of connective tissue run into the mass, forming lobules which are in some parts quite large. In other parts of the tumor no lobular arrangement is found, but the tiny threads of connective tissue run in and about the cells.

"The cells are small, round and nucleated.

"In a few places near the center of the growth the connective tissue is somewhat condensed, forming rings. In these rings of connective tissue are found large, round, yellowish masses, typical of psammoma. Under a high power ($\times 450$) no cellular arrangement can be made out, but a center with fibrillated rings about it can be seen. Many of the spaces in the center of the tumor contain nothing, but obviously they contained before section more of this psammomatous material.

"In and around the mass of small round cells are large, round, well stained plates of material, the nature of which is doubtful. No cell structure can be made out. They may represent the first stage of the psammomatous change.

Diagnosis of tumor mass.—Sarcoma of the small round cell variety, with gliomatous tissue and psammomatous change.

Brain.—Every section shows round-celled infiltration, extending through the gray matter into the white. This infiltration is especially marked along the line of the blood vessels. The stroma of gliomatous tissue is well seen.

Diagnosis.—Sarcoma (glioma).

"E. R. AXTELL,

"A. S. LOBINGER."

May 10, 1893.

A few points in connection with the clinical history of the case and the results of the autopsy and microscopical examination are worthy of comment.

If a person who is suffering from symptoms of tumor of the brain gives a history of syphilis, we feel justified in looking upon the growth as being of syphilitic origin; further, should a trial with anti-syphilitic agents result in great improvement, we feel almost certain that the tumor is syphilitic in nature. We have long since learned in the treatment of growths of the brain that if improvement does not follow the use of potassium iodid and mercury, it is no proof that the growth is not syphilitic. In the case under discussion there was a distinct history of syphilitic infection, and on placing the patient on large doses of potassium iodid in connection with mercury decided improvement followed, so that for several weeks prior to the operation no convulsive movements of the voluntary muscles occurred.

The aura that preceded each attack were limited to the left side, and mostly to the parts on this side affected by the pial lesion on the opposite side of the brain. The aura connected with the sense of taste was one of the first manifested in the history of the case, and may be accounted for by the pial thickening extending over a portion of the right temporo-sphenoidal lobe.

Is it possible to determine in a case of tumor of the cortical substance of the brain whether the pia is extensively involved? When the pia is infiltrated with the growth one would expect to find severe and persistent headache, but in the case just reported headache was rarely present, and it was never severe. The most important diagnostic symptom, it seems to me, pointing to pial involvement is the presence of two or more auras occurring with or without convulsive movements. Multiple aura, occurring regularly and at about the same time, are suggestive of extensive cortical irritation, involving numerous brain centers; a condition that is probably rarely met with in tumors limited to the brain substance. It is not probable that tumors of the pia can be removed with safety to the patient, on account of the extensive infiltration of the membrane in such cases.

There are several other features recorded in connection with the case reported in this paper worthy

of discussion, but I will at present only refer to one. During the irritative stage of the growth before paresis became permanent, disturbances in sensory phenomena were well marked, most affecting heat, next tactile, and least of all, pain sense. The sensory impairment was always most distinct immediately after an attack. As infiltration of the cortical centers for the face and arm progressed, and paresis of the face became well marked, all sensory phenomena in these parts became normal, except for a variable period following an attack. One explanation of this condition might be found in attributing to the cortical substance an inhibitory influence over the "sensory centers," whose inhibition is lost when paresis or paralysis results from destruction of the cortex. Another interpretation of the phenomena may be found in supposing that other portions of the brain cortex may perform the functions of disabled areas.

CEREBELLUM CYST—ANTE-MORTEM DIAGNOSIS.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY WILLIAM C. KRAUSE, M.D.

BUFFALO, N. Y.

For the history of this case and the pleasure of having made the observation, I am indebted to my friend, Dr. Linus T. McAdam of Buffalo, N. Y.:

Name, Jacob M.; age, 36 years; height, five feet seven inches; weight, 170 pounds; complexion fair; constitution robust, well developed. Antecedents, nothing of particular note was elicited; family history good.

Early History.—The patient passed through infancy and adolescence, without any serious illness; never contracted syphilis or gonorrhea. Some years ago he suffered a slight attack of insolation from which, however, he seemed to have fully recovered.

Present History.—On October 23, 1892, the patient consulted Dr. McAdam for pain in back of the head, dizziness, nausea, peculiar revolving sensations in his head and on standing or while walking an inclination to be drawn backward. So strong were these last sensations that while the patient was in bed he would be compelled to turn on his right side, his head deep in the pillow, or while working in a stooped position he would suddenly fall backward, and on several occasions received quite severe knocks on his head. Along with these symptoms there coexisted a sub-normal temperature, slow pulse, furred tongue, loss of appetite, sallow complexion, discoloration of the conjunctivae and constipation. The patient was administered hepatic stimulants, but without obtaining any alleviation of the distressing symptoms. A few days after this first visit he again consulted Dr. McAdam and complained of great thirst and gave a history of polyuria. On examination the urine was found to contain sugar in abundance and on measuring the urine it was found that he passed sixty to seventy ounces daily. About this time (Nov. 7, 1892), he experienced considerable difficulty in walking and was obliged to discontinue all work and remain at home. With assistance he was still able to walk about the house but his gait was unsteady, staggering, with a marked tendency to fall backward and to the right.

With the exception of the glycosuria and polyuria which subsided under careful treatment, the remaining symptoms gradually became more and more severe and a consultation was held. The disease was diagnosed as of cranial origin but no definite diagnosis was reached. All methods of treatment proving unavailing and desirous of further counsel the writer was called to see the case on January 17, 1893, with the family physician, Dr. McAdam.

The patient was found lying upon a couch complaining of intense occipital pains radiating toward the vertex. On sitting up he felt dizzy, nauseated and as if his head were being pulled backward. On attempting to walk his gait was staggering, with a desire to fall to the right and backward.

Psyche.—His mind seemed to be clear and unaffected; sleep, fair.

Vision.—The strength of the muscles of the extrinsic eyes was diminished but no more than the motility to which he was subjected would warrant.

Patellar Reflex.—The patellar tendon reflexes were slightly exaggerated. All other superficial and deep reflexes were normal.

Sensation.—There existed no disturbances of the sensory nerves; trophic and vaso-motor disturbances were likewise wanting.

Ocular Signs.—Unfortunately the fundus of the eye was not examined, due perhaps to the fact that no ophthalmoscope was present. An ophthalmoscopic examination was, however, promised but failed eventually to materialize. No abnormalities whatever of the special senses were discernible.

To me it seemed clear that we had to deal with some cerebellar neoplasm, but what its nature or origin I could not say. The characteristic symptoms of cranial tumor, such as intense cranial pain, obstinate vomiting, vertigo, coupled with symptoms which we are wont to denominate cerebellar, as staggering ataxic gait, inclination to fall backward, occipital tenderness, etc., warranted the diagnosis arrived at.

Not receiving the desired promise of speedy and certain recovery, the patient sought other advice, and the history or the course of the disease was unfortunately interrupted. On the evening of March 15, Dr. McAdam was hastily called and arrived in time to see the fatal termination. Inquiry elicited the fact that for two or three weeks previous the patient developed a slight fever with occasional chills. No convulsions were noticed at any time.

An autopsy was made the following day by the writer, assisted by Dr. McAdam, with the following results: the calvarium was rather thick; dura somewhat adherent. The pia was clear, vessels not markedly injected, Pacchionian bodies small and sparse. The convexity of the brain appeared healthy, the convolutions were not flattened and the fissures were of usual depth. The cerebrium was removed; beginning cephalad, the basilar structures carefully severed, and on cutting through the right side of the tentorium cerebelli, a clear amber-colored fluid flowed into the cerebral cavity. The cerebellum was carefully removed, and in the inferior occipital fossa was found about one to one and one-half ounces of amber-colored fluid. On closer examination, the right lobe of the cerebellum was found to be flattened, boggy and considerably smaller than the left lobe. This condition was quickly explained by the presence of a large cavity in the right lobe, the walls of which had collapsed and the fluid had escaped during removal of the cerebellum. The entire right lobe appeared to have been undermined, and virtually was nothing more than the walls of the cyst. During the dissection and examination of the cerebellum the undertaker thoughtfully and thoughtlessly sponged the cranial cavity, thus depriving us of any of the cystic fluid for a more careful microscopic examination. It is therefore impossible to say just what the character of the cyst was; whether it was the result of hydatid disease, or of inflammatory or hemorrhagic origin.

My object in publishing the details of this case is not because it is an extraordinary one, or because the diagnosis was verified by the autopsy, but rather to prove that the symptom-complex of cerebellar disease is distinct enough to permit of more radical surgical procedure. The writer is not aware that much has been done in this direction; and certainly in this case much might have been gained through surgical interference.

The tendency of the patient to fall to the right and backward, and the discovery of the cyst in the right cerebellar lobe, would impress one with the idea of connection between disease and symptoms, both pertaining to the same side. Whether this law holds true in every case, I do not pretend to say. Another interesting fact was the temporary glycosuria and polyuria, its sudden appearance and its more sudden demise. Whether this was the result of pressure, or whether it was merely accidental, must be left unanswered, although I believe the former to be the more plausible.

382 Virginia Street.

SPECIAL INFLUENCES OF ALCOHOL ON THE BODY.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY T. L. WRIGHT, M.D.

BELLEFONTAINE, O.

In discussing the nature of inebriety, and the magnitude of its influence on mankind, it will be necessary to observe the effects of alcohol upon the physical body, upon the mind and upon the moral attributes.

And first, let us consider some of the effects of alcohol upon the material organism.

The influences of alcohol upon the human body are of a nature so intricate, so distracting and often so apparently inconsistent with each other, that it is difficult to classify them in a clear and satisfactory manner.

These influences might be arranged into groups representing on the one hand, drunkenness, its relations and phenomena; and on the other representing physical degenerations, with their various connections and dependencies. Perhaps as comprehensive a division of the subject as any would be as follows:

1. The effects of alcohol upon the nerves;
2. Upon the blood; and
3. Upon the physical integrity of essential organs and tissues.

This classification might no doubt prove to be defective; and the several lines and boundaries of distinction between its component parts will be, in many places obscure, or possibly lost altogether.

1. In speaking of the effects of alcohol upon the nerves, it will be proper to advert to the impression of that agent upon the muscular sense. Alcohol is carried everywhere by the circulation, and in drunkenness the functions of the muscular system are hampered and deranged. This fact arises in a great measure from the peculiar property of alcohol, which imposes a degree of paralysis upon the nervous system, in all its several parts and qualities. There is loss of muscular power, and also disorder in the functions of muscular coördination. Movements are out of proper relationship with each other. Partial paralysis from causes other than alcoholic, present when of wide application, similar appearances and defects. Take a case of general paralysis of the insane—partial, however, in degree. "This disorder," says Dr. Tuke, "is marked by loss of coördinating power over the muscles, especially those of speech and locomotion. Precise coördination of movement, such as is necessary for writing, sewing, playing upon a musical instrument, and like acquired and auto-

matic acts, is much impaired, or quite lost." This is in every particular an exact description of the muscular disabilities of a person who is drunk. The movements assumed in walking will betray the condition of a person, even when slightly intoxicated. The feet are not raised fairly and clear of the ground, and there is frequent scraping or slipping of the shoes upon the pavement.

It has been said that "the commencement of intoxication was flushing of the face, indicating that the cervical sympathetic was becoming paralyzed."¹ This is probably true in most instances. But especially in neurotic periodical drinkers, there is a remarkable deviation from this rule. When the dipsomaniac, after a season of rest begins to swallow large quantities of strong liquors, "the vaso-motor centers in the bulb and cord" do certainly show indications of the toxic action of alcohol. But they do not consist of flushing the face through paralysis. The exhibition is rather that of spasm and rigidity, not only of the muscular system at large, but of the capillary blood vessels also,—their caliber being apparently diminished.

The beginning of a season of drunkenness in the neurotic is commonly marked by paleness of the face. The features are sharp and contracted. The nose is pointed, cold and colorless. The eyes are *not* rolling and without expression, as in ordinary drunkenness. On the contrary they are steady, although quick in movement. They also are bright and penetrating. The speech is *not* inarticulate, stammering and disconnected; but words are clear cut, perhaps "clipt," and evidently of spasmodic utterance. The muscular movements although somewhat constrained are not staggering, incoördinate and uncontrollable. In fact, while large quantities of alcohol may have been consumed, the appearances of intoxication which are the outcome of paralysis, are not always speedily developed. The paralytic stage of drunkenness may not appear for many hours in the neurotic drinker; though of course that is not the rule. The primary effect of alcohol upon the neurotic inebriate may be that of shock. This alcoholic condition is not without its important bearings upon the question of inebriate responsibility; for as long as it continues there is danger of violent and unreasonable outbursts of rage and hate. The consequences may be tragical; for there is an unnatural exaltation, both in the power and disposition to wreak vengeance for fancied wrongs. Dipsomania has been described as an insane exhibition among a group of insane exhibitions—all symptoms of a central disease. "The opinion which would make of dipsomania a separate disease, can not stand against a complete study of the facts. It is a detached page in the history of the patient's disease which can not be understood if studied by itself."² Another authority says: "It seems to me more correct to regard dipsomania as a symptom belonging to a general disease."³

The action of alcohol upon certain peripheral nerves marks it as a poison. A long and persistent course of drinking is liable to produce neuritis in one or more localities in the organism. This may prove destructive to the integrity and life of the special nerves affected. Herein alcohol acts in a manner similar to other tissue poisons—similar for instance, to lead and arsenic. The plantar nerve, the poplit-

¹ Buzzard

² Magnan.

³ M. Foville.

en), the musculo-spiral, the tibialis anterior, are some among the nerves for which the alcoholic poison displays its peculiar affinity. When the drinker loudly complains of pains in his legs and feet, and talks of rheumatism and neuralgia, the probability is that he is suffering from alcoholic neuritis in his lower limbs.

Among the larger and more prominent nerves which may come under the toxic influence of alcohol, are the phrenic nerve and the pneumogastric.

To the evil influence of alcohol upon the vagus, is attributed serious irregularities in the heart's action. Chronic pulmonary catarrh also, with paralysis and stagnation in the smaller and more remote bronchial tubes, may be referred to a kindred origin. It is believed moreover, that the fatality of pneumonia so remarkable in the drunkard, is largely owing to the injury inflicted upon the eighth pair of nerves by the alcoholic poison.

The first indication of alcoholic neuritis is change of sensibility—there frequently being severe pain. But the morbid feelings may vary. It is possible that they may become sources of troublesome hallucinations and of true insanity.

The destructive effects of the alcoholic poison in neuritis may be seen in the condition of the nerve after the disease has run its course. One description declares: "The lesion of the nerves consisted of granular degeneration of the myelin, then partial removal of the products, causing varicosity of the nerve fiber, and lastly, complete disappearance of the degenerative debris, with collapse of the sheath."

The alcohol of wine it is said, does not produce the nervous degenerations herein described. Since the discovery of distillation, and the enormous consumption of distilled spirits during the last two hundred years, wine has lost the position of respectability once accorded to it by many of the ancient writers. It is now looked upon with suspicion as a substance capable of leading the unwary into habits of vice and profligacy that were impossible before the discovery and use of the concentrated alcohols of modern days.

The disturbing influence of the paralysis of alcohol upon the normal display of the inhibitory nerve functions is generally recognized. Still, the facts and evidence on that subject are something obscure and incomplete; and they will not justify any labored effort towards detailed and specific description. The paralyzing (anaesthetic) influence of alcohol upon common sensation appears to have been known in the most remote periods of time. This is, in many circumstances exceedingly seductive; and yet, in its effects upon the mental and moral attributes it is often of very great injury.

2. In discussing the several divisions of our subject, a very brief synopsis of the more obvious effects of alcohol upon the blood is all that can now be offered in that connection.

A striking effect of alcohol upon the circulating fluid, is the production of changes in the appearance of its red corpuscles. They suffer shrinkage, and often a material change of form. Their color too, is affected, and they become darker under the alcoholic influence. When alcohol is mixed with blood, the red portion of the corpuscle may escape from that body altogether. The globules are deprived of their power to perform their functions completely and physiologically. They are incapable of absorbing

and distributing the amount of oxygen necessary for the healthful supply of the bodily structure. In other words, "the blood globules when impregnated with the toxic spirit, have lost the property of transforming all their hemoglobin into oxy-hemoglobin." Alcohol displays undoubted power over the white globules also; but the insignificance of its effects are not so readily demonstrable upon them as upon the red bodies.

One of the consequences of the toxic influence of alcohol upon the red corpuscles is the undue collection of carbonic acid within the organism. The retention of a portion of this acid is the subject of various hypotheses and explanations. It is said, for example, that a part of the oxygen inspired combines with free alcohol in the circulation, converting a portion of it into acetic acid.* This leaves an insufficiency of oxygen to properly change the character of the blood corpuscles from venous to arterial. The theory, however, does not account for the shrinkage, and other structural changes which occur in the red globules when brought strongly under the influence of alcohol. It is not therefore, simply a matter of defective balance, or of deficiency on one side or the other, but the influence of alcohol upon the red blood corpuscles appears to be really that of a poison.

The harmful retention of carbonic acid in the human body when it is under the alcoholic influence, depends upon more causes than one. The operations of alcohol are always complex. The elimination of carbonic acid by the lungs is impeded by overcrowding the capacity of those organs. The enforced exhalation of alcoholic vapor interferes with the normal ability of the lungs to expel the poisonous acid. The toxic qualities of the retained gas produce general uneasiness and also special distress. The headache which follows alcoholic intoxication is peculiarly violent; for the blood vessels of the brain are loaded with effete and noxious material. But a very serious complication that may arise from the influence of alcohol, consists of the accumulation of large quantities of fat in different parts of the organism. This may be owing to the fact that the constituent elements of alcohol, as well as of the waste and effete material in the blood, may undergo certain slight changes which result in the formation of fat. In the chronic inebriate, fatty degenerations of the liver, heart, and elsewhere, are liable to appear; and these in many ways provoke functional irregularities.

A deficiency of oxygen in the system may favor the establishment of the gouty or the rheumatic diathesis. "There is no possible chance of relief to those who are inclined to the lithic acid diathesis, if they arrest oxydation by the use of stimulants and narcotics. Arrest that oxydation by the use of alcohol, and you add to the amount of unhealthy waste which has to be removed. Lithic acid can only be removed by oxydation."

Intimately associated with the deficiency of oxygen in the blood of the drunkard, is the low temperature of his body. While alcoholic paralysis exerts—no doubt by its inhibitory force—an influence in the reduction of animal temperature, the incapacity of the red globule to absorb oxygen and to eliminate carbonic acid, exercises an unquestionable tendency in the same direction. In profound drunkenness heat has been known to fall as much as 3° F.; and it has been shown that in some instances the normal tem-

* Beaumont.

* Alfred Carpenter.

perature has not been restored for three days. The complaints of the drunkard himself (upon emerging from his condition of anaesthesia) indicate very uncomfortable sensations of cold. When the inebriate begins to arouse from his torpor and stupidity, he is invariably chilly and shivering. He draws towards the fire, or hastens to protect himself with an abundance of bed clothing.

It appears to be a fact that alcohol may reduce temperature through the force of its paralyzing and anæsthetic properties. It is a question with some whether the reduction of temperature through the establishment of toxic and pathological states of the blood is not probably as injurious in one direction as it may be beneficial in another. In the high temperature and nervous irritation of typhoid fever, the effects of a topical application of alcohol (diluted) are sometimes of great value. The application should be quite extensive over the abdomen. The local anaesthesia will not only quiet superficial nervous excitement, but it apparently extends to the subjacent tissues. Under this treatment the morbid temperature will materially abate. Diluted alcohol may also be applied to the aching head and to the burning feet and hands. This procedure may accomplish valuable results without interfering with the normal functions of the blood globules. Should a degree of intoxication be induced, it may be remembered that abstractedly, intoxication may exist without a poisonous impression affecting the essential constituents of the blood; which fact in the reduction of morbid temperature is a point of no small importance.

In the hard drinker a portion of the alcohol finds its way into the blood and remains uncombined. It has a powerful affinity for water. It is speedily found in every part of the bodily structure. Of course much of it enters the system through the portal vein and the right side of the heart. But alcohol also seems to *diffuse* itself throughout the organism directly. It is in the breath immediately. Emesis shows that it remains in the stomach for a very brief season indeed; while giddiness, confusion of thought and movement—in short, *drunkenness* shows that alcohol mounts at once to the brain.

When there is a certain excess of alcohol in the system, the movements of elimination may proceed with a good deal of vigor. But when the excess is removed, there remains a portion apparently in a kind of static condition. At all events purgatives, diuretics, diaphoretics, the lungs themselves, appear to exercise a limited power only in its final disposition. It is not unlikely that certain structural degenerations may be connected with this state of facts; and especially fatty accumulations and other hyperplasias.

Delirium tremens is indicative of a brain saturated with alcohol. The natural wetness of the brain, containing as it does a very large proportion of water, probably invites the presence of alcohol more urgently than is the case with many other organs. However that may be, it is an opinion widely held that in delirium tremens there is a direct poisoning of the system at large, and especially of brain tissue, with alcohol pure and unchanged.

3. Alcohol has been called the "genius of degeneration." Some of the prominent changes in the structure of important organs, when the outcome of alcoholic impression, are indeed of great interest, and

a brief notice of them will not be unprofitable. And first of the heart:

The heart of the inebriate at first is made tense and full by alcohol, but is easily depressed. Under this depression, however, the circulation becomes of a character that has been termed *rotten*. The continued use of alcohol tends to permanent enlargement and dilatation of the heart, with stretching of the valves—especially the semilunars. There is also distension of the arterial system throughout, leading to loss of elasticity. There may be a feeble, large heart, dilated arteries, enlarged and bulging veins. The corporeal mechanism of the heart is, in fact, changed altogether. Such a condition of the circulation would necessarily occasion much uncertainty both of the mental and bodily functions."

Again: In the fatty degenerations common in alcoholic inebriates, both in the light daily drinker and in the habitual drunkard, the heart is frequently implicated. The substance of the heart is permeated with fat globules, and its strength and endurance are impaired.

It is believed, moreover, that the structure of the heart may be seriously affected in consequence of alcoholic degeneration of the eighth pair of nerves.¹⁰ The muscular tissue of the heart, it is supposed, may undergo shrinkage and atrophy from this cause, in a manner similar to the shrinkage of the leg from the toxic influence of alcohol upon the nerves there distributed.

The heart may also become exhausted through its too frequent and irritable pulsations in the daily drinker. The physiological rest between the heart beats is not permitted to take place. In this as well as in the several degenerations already named, there is incapacity of function, and heart prostration is, to some degree greater or less, always impending.

Degenerations due to alcohol very often affect the liver. They present a variety of aspects. Fatty degeneration is the one most commonly met with. The liver is enlarged in this affection, and it is loaded throughout its whole extent with fat.

Another prominent form of hepatic degeneration is cirrhosis, producing the so-called "gin liver." The gland presents a contracted and solidified appearance with a rough surface, from which it has been also designated the "hobnail liver," "nutmeg liver," etc.

The kidneys may likewise become the seats of fatty deposit, and they too are liable to undergo the characteristic changes in structure indicative of fibroid degeneration.

A remarkable property of alcohol is sometimes displayed in its influence upon the connective tissue of the organism. There may be hyperplasia and considerable enlargement of this substance. This is not simple hypertrophy, however. It is a consequence of the toxic impression of alcohol. The tissue implicated in this alcoholic hyperplasia is invested with properties quite different from the fibrous tissue in its physiological state. After a season of enlargement, it takes on a process of contraction. This movement is so marked that entire organs are misshapen, indurated and radically impaired in function. The fibers of the shrinking mass enclose the substance of the liver, or kidneys, or other organs in their embrace; and the outcome is the gin liver, the kidney with interstitial nephritis, and the like disasters elsewhere. These phenomena are the direct re-

sults of the poisonous qualities of alcohol—there is nothing normal nor physiological about them.

The drunkard's brain has an abnormal amount of serum in it. This is owing, in part at least, to atrophy; and it "resembles in this particular the brain of the senile condition—of old age. The convolutions look small, the sulci deep, and in most cases the pia mater is easily removed."

The membranes of the inebriate brain, including the dura mater, are often thickened, and they may display other indications of organic disease. "The structural lesions of the brain show patches of sclerosis and other evidences of injury that are due to alcohol; and, in fact, these may resemble the changes that are found in the brains of paralytics." It is true, however, that these degenerations are absent from a very large proportion of inebriate brains.

The relations of alcohol to paralytic dementia have been the subject of much controversy. There is one point, however, upon which all seem to agree in regard to that question, namely: Alcohol may become an exciting cause in the production of paralytic dementia in certain constitutions; as, for instance, when great mental labor has been forced upon a brain incapable of sustaining the strain necessary for its performance. The principle has been expressed thus (the alcoholic habit being present): "Enforced functional strain with incapacity to bear it, or disproportion between functional activity and power of resistance, may end in paralytic dementia." To this extent, at least, alcohol may be classed among the causes of paresis, and of the physical degenerations found in the brains of the paralytic insane.

Enough has now been said of the effects of alcohol upon the physical organism to indicate the nature and extent of their application. It is comparatively easy to investigate the bearings of the facts presented upon the mind and upon the moral constitution of the inebriate.

ON THE CARE OF EPILEPTICS.

Read before the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY FREDERICK PETERSON, M.D.

NEW YORK CITY.

Professor of Nervous Diseases in the University of Vermont; Instructor in Nervous and Mental Diseases at the College of Physicians and Surgeons, New York; Attending Physician to the New York Hospital for Epileptics; Pathologist to the New York City Asylum for the Insane.

The care of epileptics really includes their medical treatment as well as all other kinds of help extended to them. But medical care, such as it is, has been given to them for some thousands of years, and yet without adding much to the happiness of individuals under treatment, or accumulating much evidence of positive value concerning medication in epilepsy. Our results have been, indeed, almost valueless: for, with all our dosing with bromids, borax, belladonna and so on through the alphabetical index of the Pharmacopœia, it is extremely doubtful if in ordinary practice 1 per cent. of the cases of idiopathic epilepsy are cured. Besides the practical incurability and hopelessness of the disease, its victims have suffered untold sorrows in the way of negligence and ill-treatment at the hands of the communities in which they live.

It is a peculiarity of this disease that the seizures may be momentary or may last for a few minutes

only, recurring sometimes frequently, sometimes daily and sometimes months apart, thus robbing the sufferers of their consciousness and faculties for brief periods of time at long or short intervals. Between the attacks they may be as rational and as well qualified for all the vocations, duties and social privileges of life as any other human being.

These facts do not concern only a few members of the community. Epilepsy is a widespread disorder and it has been calculated that one person in five hundred is thus afflicted. Thus there would be in the neighborhood of one hundred and thirty thousand such unfortunates in the United States alone, and over twelve thousand in the State of New York. Even supposing this percentage to be exaggerated to a very great extent and that the actual ratio were one to one thousand, the number of epileptics would still be enormous and would constitute a large part of our defective classes.

Outside of the efforts, thus far comparatively futile, of physicians to alleviate their purely physical infirmities, and to reduce the number and severity of the attacks, nothing has been done until late years to provide for their mental development and to meet the peculiar conditions of life which they are called upon to endure. Thus, no general hospital will receive such cases for treatment, because of the incurable and unpleasant nature of their malady. While much of the time thoroughly capable of acquiring an education, they are debarred for obvious reasons from the schools; the churches are closed to them; very few care to employ epileptics in shops, stores or offices or are willing to teach them trades. Few epileptics are at liberty to enjoy the companionship of their fellows, who are rather inclined to shun their unfortunate brethren. Thus, every avenue for mental or moral development, for occupation, for association with the rest of mankind is closed to them. They are even burdensome to their families. It is little wonder, then, that many of them grow up dull and ignorant, intellectually feeble, morally depraved, irritable in temper with tendencies to retrogression and degeneration rather than to advance. A few of them become insane and are sent to insane asylums. Others are not insane, but, ill adapted for existence under such miserable conditions, drift to the only homes offered to them, the almshouses. The almshouse and the asylum are the only refuge when abandoned by their friends. In the State of New York, for instance, where there are twelve thousand epileptics, some four hundred or more are in insane asylums, and some six hundred in the county poorhouses. The rest of them are scattered throughout the State in their own families, among the rich and the poor, in ratio to the population and to the relative proportion of these classes. Many are so slightly affected that they are able in spite of their seizures to pursue some of the ordinary vocations of life. Thus, I know personally of a doctor, clergyman, several bookkeepers, a bank president, a stockbroker, several clerks, some dress-makers, shoemakers, masons and a telegraph operator, who are epileptics, and yet able to carry on useful pursuits, albeit under adverse conditions. To all of us are familiar certain well-known historical or literary characters in whom epilepsy failed to restrict the development of their genius, such as Cæsar, Napoleon, Molière, Petrarch, Dostojewsky and others.

It would seem, therefore, from the above facts that, although there is such a thing as epileptic insanity, the proportion of insane epileptics to sane epileptics is very small, much less than 10 per cent., taken at the utmost, and that this ratio may be reduced by affording these unfortunates such opportunities for mental and moral development as are enjoyed by other and more happily situated citizens; and not only may the percentage be reduced, but the comfort and prosperity of all epileptics be increased by proper provision on the part of the State or through private channels such as institutions of a peculiar character adapted to their peculiar needs. A large public hospital is very far from meeting their requirements; for as has already been shown, medicinal treatment is uncertain and unpromising. Insane asylums should receive but very few, and almshouses none at all. What is demanded is an institution on the community or village plan, where medical treatment (such as it is) may be given to every member and where every sort of education, employment and social privilege commensurate with his needs and conditions may be extended to every beneficiary.

The colony system only can attain this object. A colony for epileptics is not an impracticable scheme proposed by visionaries. It is already an accomplished fact. The Bethel epileptic colony at Bielefeld in the province of West Thalia, near Hanover, Germany, was founded by Pastor von Bodelschwingh, over twenty-five years ago. He purchased a small farm with one house, and with four epileptics as a beginning established a charity which for nobility of conception and success in its results has nowhere an equal. It seemed to its beneficent founder, feasible to create a refuge where sufferers might be cured if curable, might have a home if recovery were impossible, might learn trades and the great majority become educated, useful and industrious citizens. From that small beginning there has been a gradual evolution of his idea, until now there are over one thousand epileptics, resident in some sixty or more houses, scattered irregularly but picturesquely over a large farm. Every one who visits this unique colony is deeply impressed with the happiness, contentment and prosperity everywhere apparent among the inhabitants of this little epileptic world. He sees that it is no longer an experiment and the previously unanswerable objections to such aggregations are by its success answered and silenced. At the time of my visit to Bielefeld, in 1886, there were but eight hundred and twenty-five epileptic patients. The employments were numerous and varied. A school provided instruction for some one hundred and fifty pupils of both sexes. All branches were taught. The dairy and the farm and garden occupied the attention of the greatest number of the patients, especially as a large trade in vegetable and flower seeds was carried on by the colony.

Among the shops for epileptic workmen were those for cabinetmakers, painters, varnishers, printers, bookbinders, blacksmiths and foundrymen, tailors and shoemakers; and among the stores, were a grocery, pharmacy, bookstore and a seedstore. The carpenters aided in the building and furnishing of new houses. Plans and drawings for new buildings were made in the architects' room. Epileptics were employed in all the departments of industry relating to building. Books were printed and bound and

sold here, especially works for moral and religious instruction. The illumination of mottoes for hospital wards and schoolrooms, and the coloring of picture cards were features of the work performed; washing, cooking, knitting, sewing and fancy work employed many. A bureau had been established for the collection and sale of museum objects, such as antiquities, articles of ethnographic and historic interest, autographs of distinguished people, coins, stamps, bronzes, gems, engravings, etc., and specimens from the animal, vegetable and mineral kingdoms. For men alone there were over thirty different callings.

The houses presented great diversity of architecture and position. They were well separated, generally enclosed in individual gardens, surrounded by fences, hedges and many trees, and altogether exhibited the homelikeness of a country village with little or nothing to suggest the restraints or discomforts of large institutions. There was one small cottage set aside for such cases as should be mildly insane, but bad cases of actual insanity were sent to insane asylums. Everything had been thought out carefully for the perfect evolution of this little social world; not only the multiplicity and details of occupations which would give each member of the community his choice of callings, but even the avocations, games, amusements and entertainments that might tend to divert his mind from the contemplation of his misfortune. And since my visit the colony has continued to expand, to develop new and valuable features and to confer its blessings upon large numbers of persons afflicted with this disease.

Taking Bielefeld as a model, nine other similar epileptic colonies have been established in Germany, one in Zurich, in Switzerland, and one in Holland. Most of these are not conducted by the State, but are under the jurisdiction of private or church charities. None of them are altogether self-supporting but some of them approach very near to it.

It should be stated that before the founding of the Bethel colony at Bielefeld, a somewhat similar institution, though on a much smaller scale, was begun in France in the village called La Force, near Lyons. Over forty years ago a noble clergyman named John Bost established this institution and it is in a flourishing state, doing a vast amount of good and redounding to the credit of its creative genius.

It has been found in all of these colonies that no harm is done by bringing epileptics into contact with each other. They feel on an equality with their fellows in such a place, losing that sense of isolation and singularity which they can not but observe in the ordinary world as separating them from the rest of mankind. They enjoy caring for each other and being kind and helpful to their fellow sufferers. It has been noted, too, that the number of seizures almost always diminishes upon entering the new and hopeful and encouraging life begotten by the busy community.

Within two or three years, interest has been awakened in other countries in the matter of provision for epileptics, notably so in America and England, where their peculiarly sad condition had neither been noted nor considered. In 1890 Ohio took steps toward the establishment of an institution for epileptics, a commission, consisting of Messrs. J. L. Vance, C. C. Waite and one other having been appointed by Governor Campbell, pursuant to an act of the

Legislature to select a site and prepare plans for the purpose. Of various sites examined, one at Galliopolis seemed best adapted for the project and here a tract of one hundred acres was presented to the State by the citizens for the institution. To the writer, who was consulted upon the subject of site and plans, this seemed to be the best location offered; for, although an insufficient space for a large institution, there was plenty of land adjacent which could be subsequently added to the original tract. Contrary to the advice of the writer the architect felt obliged, probably owing to the demand of the community of Galliopolis for an institution of striking proportions, to group the buildings on a symmetrical plan, such as is frequently carried out in the public establishments for the insane. The Ohio epileptic hospital is built on the pavilion or cottage plan, a large number of these being grouped about the center or administration building. It will, therefore, not meet in this important particular the requirements of a colony for epileptics, although in respect to provisions for school buildings, shops and the like, an effort has been made to fit the institution for the particular kind of care needed by this class. The name of the institution for epileptics in Ohio is also unfortunately chosen, for it is called, "The Asylum for Epileptics and Epileptic Insane." The corner stone was laid with appropriate ceremonies November 12, 1891, an interesting address and historical review being given by General Roeliff Brinkerhoff, president of the Ohio State Board of Charities. Three of the buildings were completed and made ready for occupancy in 1892 and nine additional cottages are now in course of construction, the last Legislature having made a liberal grant for the purpose. In California, detached buildings are being erected upon the grounds of the California Home for Feeble Minded in Sonoma County, with the view of accommodating the epileptics dependent upon the State for pleasant quarters.

Active measures are being carried out also in Massachusetts, Pennsylvania, Wisconsin and Illinois for the purpose of securing State care and separate provision for the same class of unfortunates.

Next to Ohio, the State of New York has manifested the most interest in her epileptic dependants, and in the winter session of 1891-92 a law was passed by the Legislature making the State Board of Charities a Commission, to select a site and prepare plans for an institution for epileptics. The law was authoritative in requiring the tract of land secured for the purpose to be four hundred acres or more in extent, and the whole scheme of buildings to be arranged on the colony or village plan. A committee of the State Board of Charities, consisting of Messrs. Oscar Craig, William P. Letchworth, and Peter Walrath, has been busy all of the past summer and autumn (1892) in examining a large number of localities which they were invited to inspect by the officers of various counties. In their report made to their Legislature on Wednesday, January 11, 1893, the State Board of Charities unanimously recommended for the proposed colony a site in Livingston County, consisting of over eighteen hundred acres, the property of the Shakers, now known as the Sonyea Society of United Christian Believers. The Shakers have dwindled in numbers to such an extent that they decided to give up this colony and rejoin the mother colony near Watervliet,

N. Y. The land is conveniently situated in the Genesee Valley, near the town of Mt. Morris and in one of the finest regions of the State. It is exactly fitted to meet the wants of a model colony for epileptics. It is traversed by two streams. One of these, the Casabaqua Creek, flows through the middle of the land in a deep gorge, with a fall of one hundred feet. This gorge and creek give immense advantage for the complete separation of the sexes in the colony life. The supply of water is abundant and the conditions for good sewerage perfect and adequate in every respect. The Western New York and Pennsylvania railroad runs through the land, and two great trunk lines, the Erie railway and the Delaware and Lackawanna railroad are within a mile of the proposed colony. The soil is exceedingly fertile and well adapted for all manner of agriculture, horticulture, the production of berries and fruits for canning industries and the raising of garden produce and seeds of all kinds. It has some stone and brick-clay, which will prove useful in the development of certain forms of outdoor employments. It already contains scattered buildings for the accommodation of three hundred patients.

The law which was introduced at the last session of the New York Legislature embodied provisions for the purchase of this tract of land and also for the methods of management, government and admission of patients to the colony. As some of these may be useful to those interested in the establishment of similar institutions, a few of the chief points will be mentioned here:

The name of the institution is "The Sonyea Colony." Thus, any direct reference to its object is avoided in the title. The word "Sonyea," is an old Indian word, meaning sunshine, and is historical in that this point was once the site of an ancient Indian village of the same name. For the present all insane epileptics are to be excluded, but probably ultimately there will be some building for the insane, especially for such as become mentally deranged temporarily while residents of the colony, since their removal from the happy influences of the community system to an asylum for the insane would be very depressing and tend to retard rather than promote their recovery.

There will be nine managers appointed by the Governor, two of whom are to be women and two to be physicians. They are to represent the eight judicial districts of the State of New York, an additional member to represent the city of New York.

The colony is to have a medical superintendent, steward, matron and such teachers and other assistants as are necessary.

The main object of the colony is to provide for the indigent epileptics of the State, but private patients will also be admitted to an extent to be determined by the Board of Managers. Epileptics of all ages are to be received and cared for; minors are detained by authority delegated by the parents or guardians; adults are free to go or remain, as they choose, there being no deprivation of liberty of any kind by methods of legal commitment, such as are necessary in asylums for the insane. The charge for maintenance of indigent patients is to be borne by the State and a limit of \$250 per annum per capita is established by the law. But it is expected that the colony will eventually become, to a very great extent self-supporting.

Patients that become insane are to be sent to asylums in the districts from which they come, in accordance with the lunacy statutes.

A special pathologist to reside in the community and devote his sole attention to the discovery of the causes and cure of epilepsy, is one of the features ultimately contemplated in connection with this great institution.

This bill was, unfortunately, vetoed by Gov. Flower for reasons best known to himself, and the humane measures for the relief of the thousand epileptics already upon public charge in New York State is therefore postponed for a year or two.

The care of the epileptic population is then summarized as follows:

All are to be treated in accordance with the usual regulations as to diet, hydrotherapy and medicinal agencies, with the hope that in this way between 1 and 6 per cent. of them may be cured and the disorder in a larger per cent. ameliorated.

Out-of-door employment in agriculture and kindred pursuits is to be provided in abundance. All manner of trades and occupations are to be carried on in an epileptic community, organized on the village plan. Facilities for education are to be afforded to almost every extent.

Amusement and entertainment and the enjoyment of social intercourse are to be privileges from which no epileptic will hereafter be debarred.

In this way the happiness of a large number of these miserable creatures will be materially increased, in spite of the distressing disease which they are called upon to suffer, usually for the whole of their lives; and though medical agents applied to their malady may prove inefficient, their fate can never be as wretched and hopeless as it has been throughout the world heretofore.

Although it is not given to every epileptic to describe his own sufferings as Dostojewsky does in his novel "The Idiot," or to delight the world with music as did the epileptic, Handel, or with comedy as did Moliere, or with poetry as did Petrarch, or with military exploits as did Caesar and Napoleon, or with religion as did Mahomet and St. Paul, still it is a consolation to those afflicted with this malady to show that epilepsy and genius may coexist, and that the possession of the disease does not necessarily lead to mental and moral degeneration. The patient may not reach the highest position among mankind, but under the new dispensation he will not be withheld from any attainment in education, nor prevented from exercising all of his capabilities for his own support and for his own welfare and happiness.

ABSTRACT OF NOTES ON THE TREATMENT OF EXOPHTHALMIC GOITRE.

Read before the Section of Neurology and Medical Jurisprudence at the Forty-fourth Annual Meeting of the American Medical Association.

BY J. MADISON TAYLOR, M.D.

NEUROLOGIST TO THE HARVARD HOSPITAL; ASST. PHYSICIAN TO INFIRMARY FOR NERVOUS DISEASES; PROFESSOR OF DISEASES OF CHILDREN, PHILADELPHIA POLYCLINIC, ETC.

Dr. Taylor takes up the subject of exophthalmic goitre as understood at the present time; reviews its relationship to other vascular disturbances, associated with enlargement of the thyroid, as myxoedema, cretinism and acromegalia. He does not see that at present the thyroid physiology warrants any large measure of hope that we shall treat this malady through thyroid juices, as in the case of the other disorders mentioned, and yet promises to explore this field later. He confines himself chiefly to the analysis of a number of cases long under his care, some of them for many years, and most of whom are well, summarizing the means through which these were improved. The treatment of maladies which demand but little constant supervision, and yet require prolonged watchfulness, is more or less difficult and unsatisfactory because such cases wander away; will not persist in treatment; and from their nature of unhopefulness have a tendency to fall into the hands of other medical men and have their treatment changed; also the exigencies of labor, fatigue, changed surroundings, etc., make it difficult to pursue any consistent plan, even with those inclined to be faithful. He takes the ground that this disorder is capable of much more hopeful treatment than is generally thought; that most cases are enormously improved, if rightly handled; that many get well.

The question of treatment is chiefly considered from the standpoint of his own experience. This consists in:

1. Regulated rest, with carefully graduated activities as time and circumstances warrant; systematic measures directed to the upbuilding of the general health; careful attention to nutrition, recognizing the trophic elements in the disorder.

2. Careful attention to vascular conditions, which are most noticeably at fault and which demand the most constant treatment. This consists of varying measures, regulating vaso-motor activities, as well as loss of nervous force through the easily disturbed nervous balance. This is done through attention to the skin from the surface by means of carefully regulated measures from without, and next the re-

view of certain remedies which seem to exert a control over the constant tendency to vaso-motor or neuroses, both superficial and deep.

3. To search out constitutional defects and remedy these; eliminate accidental poisons, either diathetic or temporary; eliminate toxins, as of internal sewage poisoning, which has a very direct bearing.

4. The regulation of the nervous or emotional balance by careful attention to the habits and environment of the individual, carefully regulating, so far as is possible, the habitual emotional strains and the possible ones, making much of moral teachings to those whose will power and mental equilibrium are gravely at fault constitutionally, and as inevitable entanglements due to months or years of suffering and susceptibilities.

5. A careful consideration of such measures as are regarded as specific, as electricity, of which much has been made by many writers, but whose value consists chiefly in the system and encouragement which is thereby exerted over the disordered emotional states.

Finally, a summary of the cases under observation when the original paper was written in 1888, the report of a number of others seen since then, and a careful review of the symptomatology and recent means of treatment.

A METHOD OF LOCALIZING POINTS IN THE HEMISPHERICAL GANGLIA.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY WILLIAM FULLER, M.D.

GRAND RAPIDS, MICH.

I will present to the Section the result of my work in the line of the subject given which I think is of value, since it enables one easily and expeditiously to locate any part of the surface or internal structure definitely, and with a precision that can be arrived at in no other way. I have hardened a brain with great care so as to maintain the natural shape as nearly as possible. The lateral halves were separated in the median line and each embedded in tallow, taking care to place each half in the same positions in the boxes surrounding them. Each half was carefully sliced by a gauge so that the slices were three-sixteenths of an inch thick and perpendicular to a line in the long axis of the brain, which was seven inches in length, making thus thirty-seven slices of each ganglion. The right ganglion was cut three thirty-seconds of an inch behind the left and photographs were taken of the divided surfaces of each slice. By this means I have obtained photographs of seventy-four vertical transverse cuts of the brain. The left side of the picture seen in the album is therefore three thirty-seconds of an inch behind the right, throughout the series which I now present for your inspection.

I have here a model which is roughly made to illustrate the principle of localization. We will suppose that the slices here represented are equal in thickness; the external markings are faithfully delineated and with photographs of the sections pasted upon the sections, the entire anatomy of any point beneath any portion of the skull can be taken in at a glance. To find as near as it is possible any point within the brain, it is only necessary to draw a line from the exterior angular process to the occiput,

divide the line into an equal number of spaces with the model, and the slice of the same number on the model will disclose the anatomy of any point on the skull, or direct the position of any point required to be found as well as the relative positions of the internal structures. Prints of these photographs properly numbered would, in my opinion, be useful for the delineation of gross lesions of the brain for publication, which would be a means of familiarizing the profession with the anatomy of the brain, and would moreover assist each of us to understand the other. Suppose, for instance, that a lesion is delineated upon a certain section definitely localized by a model and extending through a certain number of sections, it appears to me that we could perhaps some time arrive at a just conception of the function of the various parts of the brain. There is little interest at present taken in the post-mortem appearance of the brain on account of general ignorance of its anatomy and from an unsatisfactory knowledge of its functions.

I have been interested heretofore chiefly in surgery; I have given some attention to the surgery of the brain, and I will take this occasion to rectify a mistake into which the profession has fallen. It is accredited to a French surgeon that he was the first to introduce surgery into the treatment of mental defects. The fact is, however, that in 1877 I made the first craniectomy for the relief of idiocy, which was published in the *Canada Medical and Surgical Journal*, of January, 1878. I not only operated upon two cases at that time, but also published a paper upon the causes of idiocy and other conditions of feeble mindedness. The publication of these cases was widespread, and the operation was ridiculed in both America and Europe in medical journals and by the press. If there is any credit in the way of priority in the procedure, it belongs to me, since it was I who was the object of the ridicule. I think, however, now as I did then, that the operation is of little benefit to the idiots or to the surgeons either, but that it is suggestive of a fact which may be of the greatest benefit to mankind, by giving material for reflection to the theologian and the educator, and for the instillation of charity into us all. When all men are practically convinced that mentality depends upon physical conditions for its manifestation, mental defects will be regarded as diseases of the body now are; proper remedies will be sought, pity will take the place of anger, science will furnish texts; the church with all other human things will perish, religion will reign in its stead, and a school system will be established upon reason; our children will then grow up into perfect adults instead of being precipitated into early graves and crowding asylums and prisons as at present. The peculiar symptoms manifested by disease and post-mortem appearances are interesting material with which to educate astute physicians; but it is a sort of cannibalism after all that one should be sacrificed that another may be great. It is for us to initiate a revolution in mental sanitation, since those to whom this duty is intrusted are too bigoted to see when facts are plainly presented for their consideration.

THE CHAIRMAN—This is a matter of very great interest. I especially commend the practical suggestion about making brain examinations. The photographs will bear careful examination. The work shows a great deal of industry and skill on the part of Dr. Fuller.

DR. H. H. DONALDSON, Chicago University—It was last winter that I first had the opportunity of seeing Dr. Fuller's preparations, and I have not seen the one which is here upon the table before. Those which I have seen are exquisite casts of preparations from the dissected hemisphere, showing the course of the white fibers and a number of points than which I have never seen any better preparation. This is an idea which, I think, has been floating in the minds of a number of people for some time, but it has only been realized as regards the brain by Dr. Fuller, so far as I am aware. There is a French model which shows an enlargement of the medulla, which has been arranged in somewhat the same way, but the model has been magnified ten diameters and the magnification is in itself a disturbing factor; and there is no doubt that the student and others interested in the state of the central nervous system would be able to derive great advantage from the study of a model of this kind. I may add that in the Anthropological Building at the Exposition, Dr. Fuller has consented to exhibit a full series of his preparation.

THE CHAIRMAN—I would like to say that these sections have interested me very much, as I have occasion to do some postmortem work in this line from time to time, and it seems to me an admirable way of localizing, and it points out the way of describing the situation even of small lesions and of the beginning and ending of larger lesions; it would be well, I think, if Dr. Fuller would publish a careful statement with the accurate reference of certain of these sections to the position on the surface of the brain where they are met. Often it is important in describing a lesion of a ganglion and particularly in the interior of the brain to have not only the transverse positions, but also the exact position and extent of the lesions. This system should be carried out in three directions, at least, to be perfectly accurate and advantageous; that is, horizontal sections and sections longitudinally and transverse sections. These would answer for many purposes. Practically the number of sections is too great for book purposes or publication or to suggest as a method of record, and I should think in the sections which include only the ganglia and certain standard sections it would be important to indicate those more thoroughly and definitely. It is certainly a valuable method, and with additions, I believe, in the directions which I indicated of taking the sections in different directions and getting the appearances, it would be of great service.

DR. HUGHES—As far as my knowledge extends, I think that this is the nearest approach to a practical method of teaching students the regional anatomy of the brain extant. I never saw any sections or anything in Europe that approximated this in completeness. These sections and the models that the doctor makes, which are models of clearness and accuracy, I have found to be exceedingly valuable in the illustration of the anatomy of the brain in connection with my teaching in a large medical college. To those of you who have not seen the other models that the doctor makes—some of which were presented last year—I would say that these, in connection with those, enable one to make the essential regional anatomy of the brain so plain to the student that there is no excuse for his failing to have a fair working knowledge of what is necessary in the treatment of brain diseases. You will find that with the use of these models the relation of the external and internal capsule and the position of the ventricle, etc., become as familiar as could be, and as plain as the regional anatomy of the liver and

idiocy, and the secretary will note it in this manner. Certainly he should have the credit for this, as it precedes the operations and suggestions of all other surgeons on this subject.

DR. FULLER—There is one thing I would like to say; when I started in on this anatomy, I started in to interest myself; but after I went to the American Medical Association last year, there was a gentleman wanted me to see if I could repeat the experiments. I went home, repeated them, and I thought I would like the benefit out of these things if I could financially, as it would cost me a great deal of trouble and expense, and I, of course, could not manufacture them myself; but tried to get somebody to do it for me. The first thing I was asked was if I could furnish protection. I could enlist capital if I could get protection. I got a lawyer to send down a couple of sets to Washington, but of course they could not see that it was a work of art and consequently, though I could take out a patent on each piece, which was so expensive a process that I could not stand it, I could otherwise obtain no protection. I consider this the same as a book or a work of art, but they could not see it in that light, consequently I have no protection on the preparations. I thought if these things could be included as works of art, if we could bring some influence upon them to look at them in that light, I could get these things out in such a manner that everybody could avail themselves of them; but as it is now I can not get any further. You will have to do something to help me out of this difficulty.

DR. HUGHES—What do they call it?

DR. FULLER—They could not call it anything. It was innumerate. It will have to be specially mentioned and brought to their notice by some special request to influence their understanding; and I know I can take out a patent if I desire, but that would be a great deal of expense. I find that the intermediary wants about all there is in it; he wants me to work for nothing and himself to charge the profession a big price, so that I am afraid that I will have to get you to assist me in some way to have this so that we can copyright it; or else I will have to keep along in the old way and try to make a living at the practice of medicine. I think there is some money in this if it could be fixed in a way so that I could do something with it, and it will be of some benefit to the profession. If you could make some recommendation to assist me in getting those things copyrighted instead of patented, I would try to do all I could to present the profession with something so that they could teach students these things easily.

THE CHAIRMAN—I do not see how we could take any steps in this matter.

DR. FULLER—Books are copyrighted; I do not see why I could not copyright this.

THE CHAIRMAN—I do not see any reason why it should not be done, but I do not know whether that matter would be helped in any way by any special action of the Association. Perhaps it is better at any rate to refer the matter to a committee than to attempt to decide it here. Certainly the Association will gladly endorse the creditable character of the work by a resolution if necessary.

DR. FULLER—The only way to get at it is to influence the authorities at Washington to give a copyright, the same as they would on a book.

THE CHAIRMAN—I would suggest that this matter should come up under the head of business; then it could be referred to a committee if it is deemed wise on the part of the Association.

DR. H. H. DONALDSON—One point connected with the latter matter: In case Dr. Fuller sees his way clear to carry this matter any further, I think it would be extremely valuable if the two types of brain could be taken, giving model forms of each type; that would be only possible, of course, in case Dr. Fuller could realize his ideal in regard to the carrying on of his work.

SANITARY NOTES AND BEAMS.

Opening Address of the Section on Hygiene, Climatology, and Topography, Pan-American Medical Congress, by the President.

ALBERT L. GIBSON, A. M., M. D.
MEDICAL DIRECTOR U. S. NAVY.

"And why beholdest thou the mote that is in thy brother's eye, but considerest not the beam that is in thine own eye?"—(St. Luke, vi., 41-42.)

These words of the Teacher of humanity which "the Beloved Physician" of the first century has recorded, are an appropriate text for the opening address in the important Section with whose conduct I have been charged in this Congress.

Time was—and that no long time—when Hygiene, the neglected Cinderella of the medical family, slunk unnoticed among menials. Now that she graces the salon her proud sisters caress her and suitors court her favor. As an old admirer of this fair mistress whose colors I have worn through youth and manhood, I may be pardoned the personal exultation that I have lived to see her suzeraine.

The ascendancy of hygiene has greated and glorified medicine without dimming the luster of any other branch, but though her cult is established, her mission is not ended with the recognition of her supremacy and the faithful following of her own ilk. To-day she turns to the people and their rulers outside the medical fold and demands the place in their councils that is hers of right. A make-shift share in the administration of the sanitary interests of the country has been grudgingly allowed, but the inexorable demands of modern enlightenment can not be satisfied until the conservator of the public health shall sit a peer among the rulers. The minister of war may build mighty engines for destruction and defense and muster vast armies and navies, which disease can disperse with a weapon so tiny that the eye can not discern and no mere military expedient antagonize. The minister of finance may fill his treasure-houses with gold and silver by the ton, which can buy human souls—honor, virtue, independence—everything but the boon of health, God's free gift to man, through which alone he can be like His own glorious image. Commerce, agriculture, manufacture, fishery, mining and all the industrial occupations of the human race, which are now the objects of the intelligent supervision of cabinet ministers, who are grand-masters of political economy and social science, can not thrive without vigor of human blood and brains and brawn, which are the machinery of these occupations; yet until this decade it has not been thought that the intelligent supervision of a grand-master of the divine science of medicine was necessary to preserve this vigorous health of the community, without which even these other ministers can themselves only imperfectly perform their own offices of administration.

When I entered the service of the Government of the United States as an officer of the medical department of the navy, nearly forty years ago, with a minimum of experience and a maximum of enthusiasm and an exalted opinion of the dignity and responsibility of my charge, which a lifetime has only intensified, I was stounded at the total ignorance of sanitary provision then prevailing in the naval service. Medical officers were curtly reminded that their opinions and advice would be asked when desired; their protests at acts that filled the hospitals and mortuary lists were contemptuously unheeded;

they were reproved for officiousness and punished as insubordinate; disabled sailors and marines were discharged and their places and those of the dead were filled without regret or remorse, but with the shameless boast that "if men die we can ship others;" like the Netherland commodore, some of whose crew had been killed by the careless firing of a shotted saluting gun, who accepted the apology for the accident with the nonchalant remark: "There are plenty more Dutchmen in Holland."

The battle-ships and cruisers of modern navies are not more unlike the brigs and sloops-of-war of forty years ago, than are the cleanly, well-fed, comfortably clad and cared for enlisted men, who go on shore daily, subscribe for newspapers and write letters; a different race from the begrimed and degraded "shell-backs," who were ordered to their work with curses and punished with brutality for offenses which neglect and ill-treatment had incited. The naval and military establishments have considered the beam in their own eyes, but civil authorities are still purblind to the necessity for organized intelligent sanitary supervision and direction, and grope for succor only under the flash-light of a pestilential visitation.

The following from a recent editorial in an influential journal is pertinent:

"Whether cholera has or has not made its appearance at Chester, which is practically one of the suburbs of Philadelphia, it is certain that the conditions reported to exist there are in the highest degree favorable for the introduction and spread of that disease. All accounts represent the neighborhood in which the alleged cases occurred as filthy beyond description and occupied by a class of persons who pay no attention whatever to the laws of health or personal cleanliness. Of course, the country now has the pleasant assurance that the place is to be thoroughly cleaned and effectively quarantined, but why were not the steps necessary for the protection of the public health taken before the resulting disease, whether cholera or not, had gained such a footing that already five persons had died from it? The time to lock the stable door is before the horses housed therein are stolen, and the way to treat contagious diseases is to prevent their appearance and not wait for them to gain a foothold and then try to stamp them out."

The Secretary-General has announced that the proceedings of this Section and its congener, the Section on Marine Hygiene and Quarantine, will constitute a special feature of this Congress. It is, therefore, incumbent upon us before adjourning to declare very positively the opinion of the members of this Section, experienced practical sanitarians from every country of the western hemisphere, that the interests of the public health must be intrusted to a department of the Government especially charged with their administration, with equal independent, executive authority, as given to other National departments. Temporary legislation under the spur of emergencies does not beat this age. As the enlightened physician seeks to prevent his charges becoming ill, so should the guardian of the public health be able to forestall those emergencies, whose pecuniary cost in money expended and wasted, in trade paralyzed and diverted, in labor and its wages lost by the sick and terrified and dead, in a single epidemic, exceeds that of maintaining an efficient sanitary service for the whole country for a whole year.

The fault of the medical profession has always been its lack of bold assertion of its rights, but it can no longer hesitate to declare to trade and commerce and agriculture and manufacture that the

health and vigor which are essential to prosperity can not be secured by their own unskilled uninformed efforts. They must learn, as the military services have learned, that powerful armies and navies are the result of able and untrammelled medical departments. It is as unwise to confide the care of the National health to a financier, however astute, as to expect a postmaster-general to understandingly control a bureau of agriculture, a fishery commissioner to best administer the affairs of the public schools, and an attorney-general to direct the mining industries. The health of a nation is a National consideration, involving international cooperation. There should be no priority nor clash of sectional interests. State lines are not respected by epidemic intruders. No State barrier can be so defensive and impenetrable that the toxiferous germ can not pass through. The precise form of administration may be left to legislation, the indispensable requisites being that it shall be National, that it shall have parity of voice and influence in the National councils; that it shall have independent executive authority under the limitations common to other departments; and that it shall be intrusted to educated and experienced medical men, who alone are competent to assume its responsibilities.¹

I have not wandered from my text in this pleading for a National public health establishment. Spasmodic tentative provisions in emergencies are nothing but attempts to discover *motes* from abroad, when the *beams* at home should first receive consideration. To parallel further and in another sense, the scientific tendency of the day is literally towards *mote-hunting* through microscopes, instead of using our human eyes upon visible abominations. The sanitarian, official or amateur, needs but look about him to be appalled at the spectacle of indifference of rich and poor, high and low, to dangers far greater than any from cholera microbes, which confront them every hour, and it may be worth our while to indicate some of these beams in our own eyes, which we complacently refuse to see, while we magnify the motes on our horizon.

The preventable disease, which kills more of the human race than cholera and yellow fever together, and in its ordinary slow process of killing lessens the productive power of a community, directly by the enfeeblement of its victims and indirectly by its demands upon members of households and eleemosynary institutions for the care of these chronic invalids—*tuberculosis*—is tolerated with as little concern as the Mongolian exhibits for smallpox, or the Creole for yellow fever or malaria. The consumptive whose traits no professional neumen is required to recognize, frequents our crowded thoroughfares, sits beside us in unventilated street cars, and at the hotel table, occupies Pullman sleeping-berths and shares the steamship stateroom, wholly unrestrained and innocently ignorant that he or she may be sowing the seeds of disease among delicate women and children. Any one may verify this who uses his eyes for the purpose along the railway and coastwise steamer routes to our invalid resorts. Within a twelvemonth, on my way to Mexico by rail, I was

fellow passenger with two invalids in the advanced stage of phthisis, en route for San Antonio, one of whom occupied the opposite berth, and the other one diagonally across the car, so that I could see and hear them coughing and expectorating, with only such attention as well-intending but unskilled relatives could render. They had no vessels for receiving their sputa, which was discharged in their pocket handkerchiefs, to be scattered over pillows, coverlets and blankets. They left the car in the morning, and I saw those same berths, it is true with change of linen sheets and pillow-cases, but with no change of blankets, mattresses or pillows, occupied that very night by other travelers, who were thus subjected to contact with a pathogenic microbe far more tenacious of life and power of evil-doing than the dreaded cholera spirillum. One has only to sit in a crowded street car on a winter day and watch the clouds of respiratory steam circling from the mouths and nostrils of the unclean and diseased into the mouths and nostrils of the clean and healthy, as the expiratory effort of the one corresponds with the inspiratory act of the other. The road is short but straight and sure from vomica and mucous patch to the receptive nidus in another's body. Who that has ever had forced upon him an aerial feast of cabbage, onions, garlic, alcohol, tobacco and the gastric effluvia of an old debauché can doubt that aqueous vapor can transport microscopic germs by the same route? Not long ago I traveled by sea from New York to Charleston, and for two nights was cabined with some twenty consumptives going to Florida. The air was chill, and they huddled around the stoves and fearfully and fearlessly closed doors and windows, until the atmosphere became stifling with their emanations and the dried sputa, which they ejected on every side. It was comparatively easy to escape during the day by staying on deck, and I slept with my stateroom windows wide open, but the curtains, carpets, pillows and mattresses had been saturated by I know not how many expectorating predecessors. I have visited fifty smallpox patients a day, have gone through yellow fever wards and stood by cholera bed-sides with far less apprehension than I experienced on that trip, yet it was one taken by many thousands of people, who would have been terrified to know that there had been a case of cholera within a mile to leeward of their homes. Recall in your several experiences the instances of members of a family, who have occupied the same chamber and bed with a gentle and beloved aunt or sister, and those of tuberculous husbands or wives, who have become ill like them with pulmonary phthisis attributed to everything but the manifest cause.

In former years, I preached a crusade against another virulent communicable disease, in the interest especially of innocent and helpless women and children, and for a time I was gratified to find that husbands and fathers began to realize from the numerous indisputable instances I was able to report, that *syphilis* might be, as it had been, contracted from combs and brushes and rough edged drinking vessels in hotels, sleeping cars and boarding houses, from pens, pencils and paint brushes, that had been held between diseased lips, from dirty, old banknotes, from street vendors' toys, from a lover's kiss, a stranger's caress, or a nurse's ministrations. Supported by an array of cases of infected children, young girls and elderly men and women, the com-

¹ The sanitary reforms were unanimously adopted in the form of a resolution by the members of the National Sanitary Association, which was held at the Hotel McAlister, New Orleans, in 1890, and reported to the National Sanitary Conference, by which it was adopted. It was also adopted by the National Sanitary Committee, which returned it with a recommendation that it be presented to the view of the Congress to be held at Washington in 1891, and which was reported thereon.

mittee of the American Public Health Association, of which I was chairman, advocated the enactment of a law, placing venereal disease in the category of other communicable affections and punishing its transmission as a misdemeanor, but there were too many of the self-righteous blind to these beams in their eyes, who thought it wiser to seek to exterminate by ignoring its existence and never uttering the name of a disease that has done more harm to mankind than all the diphtheria, typhoid, smallpox, measles and scarlet fever, which are so carefully isolated and their statistics so regularly collected and promulgated—a disease that travels with the missionary to Asia, Africa and the Pacific and decimates bodies faster than he can whiten souls.

I do not expect that all who have eyes will see as I do, or having ears hearken to what I say. The idle and perverse generation of the first century will have its following in the twentieth, and men and women will continue to do the insanitary things they ought not to do, and leave undone the sanitary precautions they ought to take despite our warning, our imploring, our advice or our denunciation. However benevolent and beneficent the hygienist's aim, this unappreciated, unrequited and often unprofitable labor is enough to deter him from what has been derisively described as only an effort to procure the survival of the unfit—and thus thwart Nature's own attempt to rid the world of them. He encounters another obstacle to success as aggravating as the disbelief in the necessity for his work. The authorities listen to his warnings and then employ their own perfunctory and superficial methods of protection. Told that absolute cleanliness is the fundamental fact of sanitation, street-cleaners are set at work brushing the surface dirt into little heaps, which passing vehicles again distribute or the winds carry into the opened windows of adjacent residences. The refuse of the household is deposited in vessels on the sidewalks of crowded thoroughfares to be emptied after a time into collecting carts, from which clouds of dust envelop passers and circulate back into the houses—*living* dust, for Manfredi found an average of 761,521,000 microbes to the gram of the street dirt of Naples, from which he cultivated pus, malignant oedema, tetanus, tubercle and septiciemia. Swarms of flies feed on the decomposing contents of exposed garden pans and buckets and carry their tiny germ laden booty into the butcher shop of the poor and the kitchen of the millionaire. Who can dispute that if the hair of the Newfoundland dog could transport yellow fever to a distant Mississippi town, and a newspaper printed in an Ohio village where smallpox was raging, could fatally infect a United States Consul in a foreign port where the disease did not exist, that a cloud of dirt, a swarm of flies, or a single fly, as Sawtschenko, Simonds and Sternberg demonstrate, can disseminate cholera and become a focus of infection, which ordinary precaution to cover and destroy the discharges and excreta of those already sick would have made impossible? Cities are reported clean whose sanitary inspectors have merely walked through crowded tenements, a hundred or more a day, and been satisfied with external evidences of brush and broom, leaving carpets and rugs unlifted, pieces of heavy furniture, with the fluff of years behind and beneath, unmoved; and closets, cupboards, pantries, storerooms, attics and cellars undisturbed. The cellars of our great cities,

and I speak with personal knowledge of many in New York, Brooklyn and Philadelphia, are greater abominations than even filthy living apartments.

The *New York Herald* of the 5th August, narrating the death of two children by falling from a window on the fourth floor of a tenement house at 201 West 61st Street, said: "To get at the bodies of her children the frantic mother had to go through the cellar of the house. There she waded through indescribable filth, almost knee deep to where her children lay, when the foul odors overcame her and she fainted." It added: "The sanitary superintendent issued an order that the cellar must be cleaned out within twenty-four hours." Do you believe that it was the only one of its kind that needed cleaning? No city can be accounted clean until its ordinances require every cellar door to be widely opened to the sun and air—that royal pair of germicides—every cellar to be emptied of its refuse, every cellar wall and ceiling to be scraped and whitewashed, every cellar floor to be taken up if rotted and sprinkled with lime if uncovered, a tedious and expensive process, but effective sanitation, costly as it must needs be, is cheap beside the outlay of a single epidemic. There are underground foulnesses in all our great cities, of which they should be rid at any cost, as where rag-pickers and bone-gatherers collect their filthy stores, and Italian street-corner fruit sellers keep their decomposing bananas, grapes and oranges, till rubbed off by dirty pocket handkerchiefs they are exposed for sale, glistening after their repulsive polish with impure saliva. If some more hunter, loth to find so huge a beam, chooses to find solace in disbelief, I might be able to shock him by declaring that I have seen the figs he munches unconcernedly, flattened in their pretty boxes in a country where syphilis reigns, by questionable thumbs moistened by equally suspicious saliva. Shall I, while revealing insanitary horrors, dare lift the sweeping train of the fair promenader, fashioned after that of women in other countries who never walk upon the streets, and show the nasty mess of spittle, excreta, mud and dust she gathers from the sidewalks upon her white skirts and silk stockings? She will not believe me, but the bacteriologist, who scoops the mud from between the cobble stones of the streets to find it swarming with microscopic life, can gather as rich a harvest of microbes from these same dainty undergarments.

Nor are these the only beams we overlook in our search for notes. Dr. Graham, bacteriologist of Starling Medical College, in response to an official inquiry by a member of Congress, reported that he was able to obtain thirteen colonies of two kinds of bacteria from one dirty, worn banknote, and the *Medical Record* of 21st of January of this year, states that a British bacteriologist discovered 19,000 microbes, including those of tuberculosis, diphtheria and scarlatina vegetating upon a single note.

Other harbors of mordant germs are the textile-factories employed in the furnishing of street cars and stages, which the chairman of the Sanitary Committee of the New York Board of Health reports as "a menace to public health by reason of their continual exposure to uncleanness and infection from the clothing of diseased and filthy passengers," which, like their grimy bodies, may be foul with the sputa of diphtheria, tuberculosis or syphilis, the disquimations of scarlatina, measles or erysipelas, the ema-

nations of typhus or the alvine discharges of cholera or dysentery. A commendable league of zealous ladies, who are seeking to prevent the abominable practice of expectorating in public vehicles, induced a few car companies to display placards, to the effect that "gentlemen are requested not to spit on the floors," but these appeals intended for beasts, who were never gentlemen, were hung in inconspicuous places or covered by other notices, and the spitters continued to discharge their syphilitic and tubercular sputa on the floor mats to be taken on ladies' petticoats and carried to their homes. The spitter and the other beast, who voids his nasal secretions where it suits him, are largely responsible for the spread of influenza, for, according to Pfeiffer, the discoverer of its bacillus, "its contagion is found in the moist secretions of acute cases in the discharges from the nasal and bronchial mucous membranes."

Further detail would be out of place in an introductory address to this Section. Let it suffice to point to the fragile spirillum of cholera, which we are exorcising by "bell, book and candle" as illustrating the dreadful *notes* of my text, and to the sturdy robust bacillus of tubercle as the *beam* we will not consider. "Cholera," says Ernest Hart, "can only be drunk and eaten. It can not be caught and breathed;" but the tubercular mischief-maker, who finds the ever open door of the respiratory passages his readiest approach, may also enter at any or all the orifices of the body. Among one thousand autopsies, Osler found 275 with tuberculosis; among 8,873 patients in the surgical clinic at Wurzburg, one-seventh (1,227) were tuberculous; the necroscopic statistics of Harris and others "show that one-third, perhaps over one-half, of the people who live to middle age, have some form of tubercular infection; and Dr. Williams of Johns Hopkins Hospital estimates that tuberculosis of the female generative organs is four times more frequent than generally supposed." (*Medical Record*, March 18.) Can any more obvious method of direct infection in these cases be imagined than the trailing skirts of women gathering tubercular sputa from the pavements?

The sanitary inspector is destined to become the most important agent of future civic administration. The perfunctory burning of a pan of sulphur in a diphtheritic chamber, the sprinkling here and there of a solution of corrosive sublimate, or the substitution of the sweeter scent of thymol, pinol or some newer "oil" for the foul odor of the privy will not then be the tolerated limit of this interference. All that science teaches and all that intelligence can devise will be exacted of him. A sanitary inspection will be a deliberate, painstaking, critical examination of nooks and corners and their disinfection, the flooding of the lairs of microscopic notes and the deluging of unsightly beams with those unstoppered, unpatented, inexhaustible germicides, air and sunshine.

Coincident with the approaching Eleventh International Medical Congress at Rome and its fitting complement, there is to be an Exposition of Medicine and Hygiene, and significant of the share accorded sanitary science in a Medical Congress representing the highest modern professional attainment, it will be noticed that of the *two* classes, which in their ensemble make up the Exposition, *two* are exclusively hygienic, to-wit:

4. Plans, models and *matériel* bearing on school management and sanitary civic organization (*ordinamento urbano*).
6. Plans, models and *matériel* for hygienic constructions.
7. Apparatus and furniture for hygienic uses in the interior of common dwelling houses and public offices on every scale.

8. *Matériel*, appliances and accommodations for the practice of personal hygiene; and

9. Plans, models and appliances for the hygiene of the working classes.

Three are partly hygienic, to-wit:

1. Apparatus, *matériel* and plans of buildings for scientific and technical investigation in therapeutics, biology and hygiene.

3. Articles and appurtenances requisite in salvage service and in *assistenza pubblica*; and

10. Books, atlases, photographs and such like, recently published and having reference to the medical, biologic and hygienic sciences.

Two only of the ten are exclusively medical and surgical, to-wit:

2. Apparatus, instruments and *matériel thérapeutique* in the various departments of medicine; and

5. Plans, apparatus and furniture for the purposes of the divisional surgeon in cities. Additional to these, special classes are devoted to hydrology and balneo-therapy, and to the Italian Red Cross Society, both of which are practical outcomes of sanitary endeavor.

I do not forget that climatology and demography, as well as hygiene, are within the purview of this Section, but what are climatology and climato-therapy but applied hygiene; and what demography but the demonstration of the results among masses of people of sanitary or unsanitary conditions? The climatologist is of necessity a hygienist. The materia medica and pharmacopœia are not his textbooks. Physical geography, meteorology, hydrology, balneology are his scriptures and gospels. The vivifying light, invigorating air and healing springs and waters his armamenta, his anodynes and hypnotics, his roborants and entropics, his alterants and excrementals. The high professional standing of the American Climatological Association, one of the constituent bodies of the Congress of American Physicians and Surgeons, and the distinguished climatologists who are with us to-day and who are conspicuous in every International Congress of Hygiene, are evidences of the place in medicine of climato-therapy, the practical end of medical climatology; that broad specialty which robs so many graves of untimely victims and makes so many heretofore without hope able, if not to take up their beds, at least to get out of them, and walk. The field of the climatologist is broad as the habitable surface of the globe—in the high altitudes of Colorado and the Alps; in the odorous pine forests of Norway and the Carolinas; on the sea shore or upon the wide waste of waters and their islet oases swept by ocean breezes.

Our American vital statistics are not yet piled high enough to form the foundation for a substantial superstructure of demography. The great caldron in which we are mixing Celts and Saxons, Semites and Aryans, with a seasoning of syphilis, tuberculosis and insanity, is simmering, with what ultimate homogeneity can only be conjectured. When immigration was a tiny stream, however muddy and noisome, poured into a rapid river of pure water, it was soon lost in the crystal fluid; but now that huge sewers are discharging their fetid pestilential torrents into a placid lake that has no outlet, the lake itself becomes turbid and unclean. Already, in the *caldrons* which are nearest the open mouths of these foul sewers and receive their floating scum—the pris-

ons, reformatories, almshouses, insane asylums and hospitals—this filthy, debased and diseased foreign element is ascendant, and our demographers have a simple task in representing its volume by numerical statistics. Dr. Frederick H. Wines, the distinguished compiler of this portion of the census of the United States for 1890, demonstrates by the indisputable evidence of figures that while the foreign born constitute only 17 per centum of our total white population, in round numbers about one-sixth, yet they furnish over one-half of all the paupers in the almshouses of the country. It is evident that the traits of the Saxon are disappearing from our National complexion, and if the proper solution of the negro question be, as suggested by certain prominent Afro-Americans, to bleach it out by admixture, we may expect the hue of our descendants to be decidedly tawny.

The most zealous demographers of this decade are the French, who have been spurred in their statistical researches to discover the causes of the too evident depopulation of France of its native races. But are we not again refusing to consider the beam in our own eyes in not giving heed to the operation of similar conditions in our own country? Dr. Billings announces that our birth rate has fallen from thirty-six per thousand inhabitants in 1880 to thirty-one per thousand in 1890. The twenty to thirty children of our ancestors, the dozen or more of our great-grandmothers, have dwindled progressively to five or six, then to three or four, until to-day one or two or none represent the fecundity of the educated classes. The *Independent*, referring to New England Puritan life, says:

"Large families abounded. According to Cotton Mather one woman had twenty-two children, another twenty-three by one husband, and a third was mother to seven and twenty. Sir William Phipps was one of twenty-six children of the same mother. Printer Green had thirty. The Reverend John Sherman of Watertown had twenty-six children by two wives, the second spouse the mother of twenty. The Reverend Samuel Willard, the first minister of Groton, had twenty children, being himself one of seventeen, as was Benjamin Franklin."

The paragraphist who can now record the case of the woman of 31 at Cold Spring who has become the mother of seventeen children in nine years, or that of the Georgia matron of 25 who rejoices in thirteen, has, in newspaper parlance, "a great find." The spectacle of impending maternity among our better classes is becoming more and more rare, and still more rare that of an infant nursing at its mother's breast. Only in the squalid quarters and purlieus of our great cities where the English language is not spoken, among imported lazzaroni and the overflow of Italian ghettos, does the process of human incubation go on as God and Nature intended. The laws of creation are immutable, and one has but to look beneath the disfigurement of female dress to recognize the evidences of imperfect physical development—in stooping unsymmetrical shoulders, in meager limbs, in narrow pelvis and flattened busts. Dr. Otis exhibited at the recent meeting of the American Climatological Association in illustration of the diametric measurements of the thorax, the profiles of a number of female chests which were supposed to be those of little girls until he explained that they were the contours of nubile young women in Boston normal schools, like her whom Solomon bewails in the Song of Songs: "We have a little sister and she hath

no breasts; what shall we do for our little sister in the time when she shall be spoken for?" My friend, Dr. Robert T. Morris of New York, has called attention to the fact that eighty per centum of all Aryan-American women have rudimentary clitorides and asks if evolution is trying to do away with this organ in the degenerative changes characteristic of highly civilized varieties of the *homo sapiens*, of which early falling hair, decaying teeth, weak mammary glands and badly balanced eye muscles are other examples. Is the sexual instinct losing its potency as a maternal factor? Is marriage only a social office for the display of finery on the bride and bridesmaids and the entertainment of crowds of gaping strangers? Is the virgin wife best prepared for conception by months of preliminary sur-excitation and feverish anxiety, and is a fatiguing railroad journey the best prelude to an act which should lead to the inception of a human being, the incarnation of a human soul? Has the function of reproduction come to be regarded only as a bestial concomitant of matrimony, and lactation its vulgar indecent supplement, and is all this attributable to physical deterioration shown by the undeveloped or imprisoned *mamilla muliebri* and atrophied mammae, and how far is this the explanation of the diminished fecundity of the Aryan-American woman? These are problems as interesting to our demographers as the depopulation of France, the disappearance of South Sea Islanders, the migration of Semitic and Mongolian races, and the effects of mal-nutrition on the indigenes of Ireland and Russia.

But, gentlemen, I shall no longer trench upon time that belongs to you. I am highly gratified at your presence and thank you most cordially for your kind attention.

Note.—The remainder of the address was delivered in Spanish, of which the following is a translation:

Gentlemen, our Friends and Colleagues from Abroad—Permit me, on the part of the members of this Section from the United States of America, to tender you a most hearty welcome to our capital. Your long travel to this city bespeaks your interest in the occasion. It is no light boast that here for the first time in its history, the medical profession of all America finds itself united in one great Congress. It was about nine years ago that a number of Canadian sanitarians claimed the right as Americans to become members of the American Public Health Association, and it was my privilege as president of that body to receive them as such. The subsequent transactions of that Association show how loyal they have been to its traditions, how zealous they have participated in its work and with what dignity they have filled its highest offices. Two years later they carried the Association into their own territory at Toronto.

In 1890, two distinguished representatives of the Supreme Council of Health of our sister republic of Mexico came to Charleston and, as Americans, likewise knocked at the door of the American Public Health Association, returning the following year in such numbers and with such a hearty welcome from their government to meet in their own capital, that the invitation was accepted, and the most successful meeting of the Association, the twentieth in its history, was held in the ancient city of the Toltecs. To-day the roll of States represented in the Advisory Council shows Illinois, Massachusetts and Tennessee, Ontario, Quebec and Manitoba; Louisiana, Quebec and Zaire in one fraternal union.

What sanitarians have done in that Association, which bears the escutcheons of its three constituent countries, side by side, this Congress aims to accomplish for the whole profession of medicine in the Western Hemisphere, uniting its members in one brotherhood, whatever their race or language, and whether their homes be on the frozen shores of the Arctic or the ill-deserts of Tierra del Fuego, among Greenland's icy mountains, in the archipelago of the West Indies or amid the perpetual gardens of Hawaii.

Physicians and brothers from the United States of all America, welcome to this your capital, which in that sweetest language spoken by human tongues, *proposui a vobis in disceptatione*.

Medico-legal Photography.—One of the recent inventions in photographic science is exhibited in the French building at the World's Fair. It consists of a reversible camera, with a special tripod enabling the operator to photograph a corpse and the surrounding area of ground in the proper perspective to an extent of about eight feet square. The tripod is placed over the object and focusing is obtained by means of a mirror at the back of the camera with an angle of 45 degrees. By this method the condition of the ground and contiguous objects in their most minute details are fixed upon the sensitized plate.

CHOLERA; ITS NATURE AND ITS CURE.

BY HENRY RAYMOND ROGERS, M.D.

DUNKIRK, N. Y.

"We have no better means of combating the cholera to-day than at any time since it became known to civilization, a thousand years ago," said a distinguished physician in a recent number of the *Review of Reviews*. "The medical profession therefore stands confronted with the appalling fact that hitherto all theories of this disease have been so misleading, and all forms of treatment have proved so worthless, that longer to trust them would be little less than criminal. Better theories and practice are urgently demanded."

The bacillus theory of Dr. Robert Koch, which was so eagerly grasped at, is now found to be fallacious. Dr. Koch himself admits that comma-shaped germs are found in the common diarrheas of summer everywhere, and he tells us: "Water, from whatever source, very frequently, not to say invariably, contains comma-shaped organisms." He is not ignorant of the fact that these bacilli are found in the secretions of the mouth and throat of healthy persons and in the dejections of hardened fecal matters. Dr. Koch also knows full well that Drs. Pettenkofer of Munich, and Emmerich of Berlin, two of the most distinguished members of the medical profession of to-day, and experts in this disease, drank each a cubic centimeter of "culture broth" containing these pathogenic bacilli without experiencing a single characteristic symptom of cholera, though the draught in each case was followed by liquid stools swarming with these germs. Hasterlik reports six cases of the same kind without any apparent results. The utter worthlessness of Dr. Koch's comma bacillus as diagnostic evidence of this disease is thus fully demonstrated.

As the result of a personal experience in every epidemic of this disease in our country since 1851, together with an experience of its effects upon my own person and a success in its treatment quite phenomenal, I am prepared to assert that cholera need be no longer the dread and scourge which hitherto it has been.

It is strange that a new philosophy of this disease which must revolutionize its theories and its treatment is now found where it never before has been sought for, but where alone it is possible to find it, viz: in the right interpretation of the symptoms which characterize the disease. This philosophy not only reveals the essential nature of this disease, but points unerringly to a more successful treatment.

The symptom of most vital importance, and the only one which is pathognomonic, is the watery exudations which find their way so profusely through stomach and intestines and skin. In fact, all other symptoms which follow this one have their origin *in it*, since, in the entire absence of *this*, neither of the others can have an existence. The most vital consequences, therefore, depend upon the right appreciation of this symptom, together with the promptness and efficiency with which its indications for treatment are carried out. This watery element is constituted of the serous element of the blood, and comes from every part and portion of the system.

The question now arises, by what process does this rapid separation of the finer element of the blood from the coarser take place? The nerves of the

system, when in their normal condition, preside over and maintain the tonicity of every organ, vessel and tissue of the body. They control the functions and processes of every part. The rapid filtration of the watery element of the blood through the now loose and patulous walls of the blood vessels indicates a loss of tonicity on the part of the nerves which permeate those walls. On account of such weakened condition of the walls of the blood vessels a general serous outflow pours from every vein and venule of the body, and the great life current is thus robbed to supply these so-called rice water discharges. At the same time the weakened vessel-walls contract with diminished force upon their remaining contents, and consequently the brain and heart fail of an adequate supply, and the more fatal symptoms and death follow. Such is the secret of the disease and its rapid and phenomenal fatality.

The rapid abstraction of a single element of the blood becomes disastrous in the same manner as when the full blood itself is lost in the more common forms of hemorrhage. It is, therefore, passing strange that this rice water phenomenon never has been recognized as a hemorrhage, with all that such a hemorrhage implies. All symptoms and conditions incident to this disease, as also the changes observed upon the cadaver, are explainable upon the hypothesis of actual hemorrhage; and we are warranted in saying, *only* upon that hypothesis.

Owing to the failure to discriminate between the actions of the red corpuscles of the blood and its white discs, its chief constituents, this hemorrhage hypothesis has not been applied in explanation of this disease. The vital forces of the system depend largely upon the action of the red corpuscles, for through these chiefly are effected the oxygenation of the blood and the consequent revitalization of the system. A small loss of this element may become quickly fatal. On the other hand, the serum or white element which constitutes the bulk of the blood performs less vital functions, and its abstraction becomes neither so quickly nor so seriously manifest. In this disease enormous quantities are sometimes separated from the circulating current without fatal consequences.

Treatment.—Since the disease is essentially a neurosis, and its controlling symptom a hemorrhage, its treatment becomes at once clearly defined, and the pure empiricism of the past must give place to a scientific treatment with vastly improved results. We must look upon the cholera hemorrhage as subject to the same general principles of treatment as other hemorrhages.

As the cholera hemorrhage occurs over so large a portion of the body, is colorless, and therefore virtually a *concealed* hemorrhage with all that is alarming which that word implies, it calls for attentions at once prompt, efficient and watchful. No painless diarrhea or painless vomiting is free from danger during a cholera epidemic, since the milder conditions of the disease often quickly change to those more grave and fatal.

Both the principles and the practice of medical science teach that position, *position*, position, is the prime safeguard in sudden and profuse hemorrhages occurring from any cause. In the treatment of cholera hemorrhage, position with the body horizontal or with the head the lowest, is quite as indispensable as in that arising from any other cause.

Position in the treatment of cholera is not simply a repose in bed with the head resting comfortably upon the pillow, and raised or lowered at the pleasure or caprice of the patient; but to be efficacious, as in its graver cases, it must be *compulsory*, and strictly maintained, *as for the very life*, until the danger period is passed. The vital necessity of position in the treatment of cholera is shown by Murray, Cunningham and other distinguished authorities when they tell us that "once sitting upright in bed sometimes causes death in this disease." Not even in the act of evacuation of the bowels should the head be raised in the more serious cases. But position in this disease is sometimes difficult to secure, as the patient, when weakened by exhaustive discharges and pain, becomes disturbed in intellect and is with difficulty controlled.

If the best results are sought for, the horizontal position should be enforced in every case of even suspected cholera. In cases of great danger the body should be inclined with the head the lowest. This position should be maintained until the blood vessels contract upon their contents, which fact is shown by an improved condition of the pulse.

In the present condition of medical science, opium and its preparations stand far above other remedies which may be employed in the treatment of this disease. No remedy is known which surpasses this one in the power to change the perturbed condition of the nervous system and close up the diminutive avenues through which the watery element of the blood and the life ebb away together. During an epidemic it is hazardous to rely upon remedies taken through the mouth, since in cholera the action of the mucous membrane often becomes changed, so that internal remedies either fail to act or are ejected. Moments are sometimes precious, as a life may depend upon the certainty of retention of a remedy and the promptness and efficiency with which it may act. The hypodermic method is here our best resource. According to the reports of cases in Asia, Australia and elsewhere, the hypodermic use of morphia has shown almost uniformly favorable results; the one-eighth to the one-sixth of a grain of the latter very rarely need be exceeded or frequently repeated. Opium and morphia *in large doses* are decidedly contra indicated *in any of its stages*; since, if these drugs are retained in the stomach, they may become cumulative and in the case of reaction they might become fatal.

For the relief of the atrocious cramps, the administration of chloroform by inhalation, together with small doses of morphia hypodermically applied, offers the most speedy and effectual means at our command. The stimulation of the brain by currents of blood sent to that organ by *position*, wonderfully facilitates the control of the cramps.

For excessive thirst, ice may be given ad libitum; and if ice can not be obtained, the coldest water in small quantities and frequently repeated. The suffering from thirst in this disease is inconceivable, and it is unjustifiable, unmitigated cruelty to withhold these necessities from the sufferer. Ice has been given freely in *every* case under my charge, and with the happiest effects.

The circulation should be promoted by the application of heat and friction to the extremities. Any further treatment may be conducted upon general principles.

En résumé: This disease, so destructive to human

life, is thus found to be most simple in its character and positive in its indications for treatment. As a problem in medical science, cholera resolves itself into a question of supply of blood to the brain and heart. If this supply be kept up, a fatal termination to this disease is not probable. Whatever course will best promote this end, therefore, must secure the most favorable results in its treatment.

The inestimable value of *position* as the fundamental idea in the treatment of cholera was first exemplified upon my own person in 1854, and has been abundantly demonstrated in the epidemics which have since occurred.

The simple theory herein advanced is found in entire harmony with the highest principles and practice of the advanced medical science of to-day. It offers results such as never yet have been realized, and places within the reach of all a ready method of treatment. This treatment may be successfully employed even without the use of medicines.

In fine, in the light of the study of this disease during forty years, both at home and abroad, such as few have had either the opportunity or the inclination to pursue, and in view of the phenomenally favorable results of treatment based upon this philosophy, I believe myself fully warranted in asserting that the rate of mortality of this scourge may be reduced to less than half of that at which it confessedly stands to-day.

The foregoing theories have been presented by the writer before the American Medical Association, the New York State Medical Societies and the Chautauqua County (N. Y.) Medical Society; also through the columns of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the *Chicago Medical and Surgical Journal*, and the *Quarterly Epitome of Practical Medicine and Surgery*.

NECROLOGY.

A Famous Irish Surgeon Dead.—Dr. T. H. Parke, who Accompanied Stanley through Africa.—Dr. Thomas Heazle Parke, a distinguished surgeon, and one of Stanley's most intimate and beloved companions in the latter's trip across Africa in 1887-88-89, is dead. He was an Irishman, his birthplace being Ologher House, Drumona, County Tyrone. Dr. Parke was only thirty-six years old at the time of his death.

He was commissioned as surgeon in the medical staff of the British Army in 1881, and from that time onward his life was spent in active service abroad. The following year he was in the Egyptian campaign and received the Queen's medal and the Khedive's star. He then went through the cholera epidemic in 1883, and afterwards was in the Nile campaign for the relief of Gordon. Dr. Parke was present at the battle of Abu-Klea, the action of Gubart and other engagements. He went across the Bayudu Desert in medical charge of the naval brigade under Lord Charles Beresford and returned in medical charge of the Guards' camel corps under Lord Falmouth.

ACROSS AFRICA WITH STANLEY.

Subsequently he crossed Africa with Stanley in 1887-88-89, and when he returned received many honors from societies, his government and the Khedive. He was put in command of a company of the detachment under Major Bartellot, which sailed up the Congo on the steamer *Stanley*. At one point of the journey, at Ipoto, Dr. Parke was practically in the power of the natives. He and his companions, separated from the main body, suffered severely from want of food.

In 1888, when at Fort Bodo, Stanley fell ill of sub-acute gastritis, he pulled him through. After this he insisted upon accompanying Stanley to the Nyanza. In the following year Dr. Parke was himself stricken down. But while suffering from fever he arose from his sick bed to minister to other invalids. When Emin Pasha was found and met with his accident, Dr. Parke attended him successfully.

It is told of Dr. Parke that when he found Lieutenant Stairs wounded by the poisoned arrow shot by the hostile natives of the Aruwimi forest, he sucked the poison from the wound.

Stanley, in his work "In Darkest Africa," gives high praise to Dr. Parke for his invaluable services and his fine character.

Dr. William Thomas White, editor for many years of the *New York Medical Register*, died September 17, 1893. He was born in Richmond, Maine, in July, 1829. He was a graduate of the New York Medical College in 1855, being a protégé and afterwards assistant to that other distinguished Maine man, the late Dr. E. R. Peaslee. He served as house surgeon to the Ward's Island hospitals for a time, going thence to the Isthmus of Panama as surgeon to the railroad. He returned to New York after an absence of eight or nine years and at once identified himself with the Academy of Medicine, the American Medical Association and others of the best organizations. He was secretary of the Academy, five years later, serving in that capacity for eight years. He was an ex-president of the Medico-Historical Society and Medical Association of New York County. His positions on the staff of the Demitt Dispensary of the Presbyterian Hospital of Charity on Blackwell's Island and of the Veterinary Surgeons College, were well and honorably administered, and some of them were held down to the time of his demise. Dr. White's membership in the American Medical Association dates from 1866. He was one of the charter members of the great New York State Medical Association, now grown to a membership of 800, and the success of the body was very near his heart. The cause of his death was referable to cardiac hypertrophy and its sequelae.

Dr. Seth Rogers of Pomfret, Conn., died Aug. 6, aged 70 years. He was the twelfth son of a Vermont farmer and won his way into the medical profession by dint of perseverance, as well as a conflict with disabling ill health. He was a man of Quaker parentage and an anti-slavery advocate before the breaking out of the war. In 1862, he took the office of surgeon to a colored regiment, organized by Col. Thomas W. Higginson, the First South Carolina Volunteers. His medical education was partly obtained at the New York University and partly at the Castleton school. He also studied for a time in Paris under Trousseau and Valleix. He visited South America in 1858 for the sake of his health. Worcester, Mass., was his home during the earlier years of his career. In 1863, he was obliged by illness to leave the army, and he went to Pomfret in order to follow an outdoor life on a farm. He was able to establish a winter practice in Florida for a dozen years, and cared for patients at his own house in Pomfret during the summer months. Although his life was one long conflict with the *pes angusta domi* and with ill health, he was a character of so much vitality and courage that he has left a record bright with honorable accomplishment.

Dudley S. Brainard, died at Osage, Iowa, Saturday, Sept. 9, 1893. Dr. Brainard was born in Williamsburg, N. Y., now a part of Brooklyn, Jan. 3, 1851, and came to Wisconsin with his parents in 1861; six years later they removed to Zumbrota, Minn. He received his medical education at the University of Buffalo, N. Y., graduating Feb. 23, 1875. After practicing a short time in Minnesota and Wisconsin he removed in 1879 to Stacyville, Iowa, where he resided until a short time before his death.

Dr. Brainard prized his profession highly and was regarded as one of the strongest men in regular medicine in Northern Iowa. At the time of his death he was a member in good standing in the county, State and American Medical Associations. He was a faithful attendant at the meet-

ings of these societies, contributing frequently papers, which were listened to with interest.

Dr. Brainard was married in 1876, and his estimable wife and two children survive him.

His memory will long be held in loving esteem among those who knew him as a faithful physician, a loyal friend, a noble man, and a Christian.

Dr. Edwin N. Colt of Brooklyn, died on the 15th inst., after a period of sixty years of almost uninterrupted family practice. He was the *doyen* of the medical faculty of his town, and it is said that there are only two survivors in New York State whose dates of graduation antedated that of Dr. Colt. He was a native of Berkshire County, Mass., having been born there on August 7, 1811. He was a graduate of the old Berkshire school, in the year 1832. He was highly honored by the community in which he lived.

Dr. Philemon Hommel of Jersey City died suddenly September 14, aged 57 years. He was an Alsatian by birth and a Parisian by education. He studied pharmacy at Paris and became the pharmacist to the Hôtel Dieu, following his father and grandfather in the first choice of a profession. Having come to America, circumstances led him to study medicine and about 1882 he obtained his doctorate. He was successful in practice, and at the time of his death was a visiting physician to the Jersey City Hospital. His death was due to pulmonary hemorrhage.

Dr. Austin K. Gould of Worcester, Mass., died Sept. 9, aged 67. He was in the volunteer medical corps during the war of the rebellion as surgeon.

He was placed in charge of one of the division hospitals at Wilderness Run. Here he was captured by the confederates and for nine months languished in the prisons of Andersonville, Florence and Charleston.

In the latter place he was for nine days under a continual fire from the Union batteries.

Prof. Lyman Bartlett How, M.D., of Manchester, died in Hanover, N. H., Sept. 15, of consumption. He graduated from Dartmouth in 1860, and from the medical department in 1863. He had been Professor of Anatomy at Dartmouth for twenty-five years, and held the place until this year, when failing health compelled him to give it up. Dr. How was 55 years old, and leaves a widow and two children.

Dr. Horatio Nelson Page of Chelsea, Mass., aged 87 years died on the 16th at the residence of his son-in-law, Charles E. Reed, in Milwaukee. Dr. Page was well known in the East, having practiced at Chelsea and Bangor, Me., for many years.

Dr. Joel Henry Cooper, father of Congressman H. A. Cooper died at his home in Burlington, Vt., aged 70 years. He was born in Windsor County, Vt., and went to Burlington in 1845, practicing medicine until his retirement about ten years ago.

Dr. W. H. Galt, health officer of the city of Louisville for the last twelve years, died suddenly Sept. 14, of "blood poisoning." He was 66 years of age and one of the best known physicians in the State.

Dr. E. F. Long, past grand master-at-arms of the Knights of Pythias of Wisconsin, died Sept. 8, at his home in Black River Falls, Wis., after a prolonged illness.

Dr. Frank W. Brown, of 51 Eliot Street, Detroit, Mich., died Sept. 9. He was a son-in-law of the late John J. Bagley and his father was a physician of that city.

Dr. William P. Buck, who was surgeon of the old Eighth Illinois Infantry during the war, died Sept. 15 at his home at Mowequa, Ill.

Dr. Abram Simmons of Cohoes, N. Y., died at that city on the 12th.

Dr. John L. Galliver of Toledo, died Sept. 18, 1893.

Dr. Edward Warren Bey of Paris, died in that city Sept. 16.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE, \$5.00
SINGLE COPIES, 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

NO. 68 WARREN AVE., CHICAGO, ILLINOIS.

All members of the Association should send their ANNUAL DUES to the
Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 30, 1893.

THE SEASON OF THE STUDENT.

Let those study who never studied before.

Let those who always studied, now study the more.

The annual pilgrimage of the medical students has commenced; some returning from summer semester with renewed health and vigor, others fresh from academy in pursuit of a new branch of science; and all classes full of enthusiasm and bold resolve. The dingy old college looks well to these youths, for in its walls are stored the paraphernalia of the amphitheater, the laboratory and the clinique. Even the musty jokes of the professors seem to have penetrated the cracks and crevices about the lecture rooms, which seem to be smiling softly to themselves as the eye of the neophyte rests upon them.

But no one better than the medical student, knows that there is a serious side to his life. He may have a rollicking, devil-may-care expression at the beginning of the term, but he knows that there are pains and penalties as well as prizes on examination days, and the former are as two to one.

The student has changed from the days of fifty years ago. Then, as a rule, he forsook the plow to follow a preceptor for six months immediately preceding the opening of the college term. He kept calls, studied anatomy in a desultory way, and occasionally assisted his preceptor in important cases. He then came to college with a fair knowledge of the routine life he intended to lead, he listened to many daily orations through the allotted period, and in a very short time received the engrossed parchment that authorized him to respectively save or slay according to his ability on the one hand, or blundering propensities on the other. Those days have passed for the American student; he may have less native keenness than his predecessor, but he has vastly more collateral knowledge. He is compelled to show evidence of previous academical study upon entrance,

and there is a strong probability that should he enter the recitation room, he will be necessarily absent on Commencement Day.

The pedagogue, too, has changed with the times; he no longer cultivates oratory, but the details of the branch intrusted to him; his speech is seldom studied, but his ideas are those born of intimate study of the subject in hand, and more than that, the fruit of a greater experience than that of his predecessors. The great increase in population has multiplied hospitals and dispensaries, until there is now little lack of opportunity for study of actual cases of any particular affection. The scientific pedagogue endeavors to allure and attract the students by class experiments and demonstrations. These have taken the place of the anecdotes that were used by all the old time professors. Our student must have his knowledge completely digested by the end of the term, so thoroughly mixed and incorporated into himself that it is his own. If he disgorges it whole, in the examination room, he will be through life a mental dyspeptic. The thorough assimilation of the knowledge poured into him also stimulates originality. "Bees," says MONTAIGNE, "cull their several sweets from this flower and that blossom, here and there where they find them, but afterwards themselves make the honey, which is all and purely their own, and no longer thyme and marjory." The modern method of teaching seeks to instill in the mind of the student the general principles of sincerity of purpose, attention to the lecturers and demonstrators; and a true student will learn modesty from the history of the art. The student also soon learns that cultivated eccentricities of manner and speech are no longer a passport to the highest standing in his class. He will gain much from the diversity of opinions he may hear expressed in the lecture rooms, and if he be wise he will follow the opinions that seem founded on reason. He will remember that the Republic of letters is a Republic and not a kingdom; for there is no king. He only commands who has reason on his side.

Few departments of the medical college are more useful than the quiz, which is not only invaluable to the student, but is made use of by the instructor to gauge the capacity of his pupils; as a young horse is brought out and exercised by his trainer, that the one may be made faster and stronger by exercise, and the other may know his gait, speed and peculiarities. But the quiz master should be entertaining and engaging in manner; the quiz "driver" is an unmitigated nuisance.

The student, to be successful, must avoid excesses, keep healthy and pay due attention to exercise while storing his mind; remembering the saying of PLATO that one must form not only a mind, and not only a body, but both a mind and a body, to become a Max.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

No greater evidence of the altered position of electricity as a remedial agent need be sought than the character of the attendance and discussions at the recent meeting of the Association in Chicago. The interested participants seemed equally divided between those who were avowed specialists of National reputation and those whose standpoint was that of the general practitioner, and it was easy to see that both the speakers and hearers appreciated the educational value of the occasion. The two days' discussion on the character of coils, induced currents, and the new sinusoidal currents produced by specially constructed dynamos, and as well the discussion on fibroid tumors and individual papers showed scientific qualities unsurpassed in any other National organization. It showed also that such technical, though practical, subjects could not be adequately considered in any other medical organization than one devoted to electro-therapeutics or in a special section of our own great Association.

The organization of this Association was due to the combined labors of BETTON MASSEY, GOELET and WM. JAMES MORTON, names all standing for what is best in the newer electro-therapeutics. To them the profession are indebted for this most important step in the rescue of electro-therapeutics from empiricism and the ascertainment of a scientific basis for its claims.

Blatant quackery had already been relegated to a quiescent position as the ever-gullible public will permit, but the work cut out for an association devoted to medical electricity was even more difficult; it was the rescue of the remedy from the hands of its avowed friends—men who intrusted a noble agency to unskilled assistants and nurses. REMAK, ERB and DUCHENNE DE BOULOGNE builded well the foundation of modern electro-therapeutics, but so much can not be said for CHARCOT, who, great as he was, was responsible for a school of "impressionists" largely recruited among French and American neurologists, whose influence was distinctly inimical to scientific electro-therapeutics.

To AROSZOLI is due the modern revival of the physical methods of ERB, and as the field of their application now invaded gynecology and other departments capable of direct study and materialistic demonstration, it became finally possible for the questions involved to be discussed by believers in mere natural phenomena rather than mysticists.

As physical questions, involving the application of measured quantities and known qualities of an important force of nature, the subjects discussed at the three meetings of the Association have proved themselves sufficiently attractive to draw large audiences, and the discussions have been particularly full and

exhaustive. In accord with recent tendencies much space was devoted to gynecological questions, though it may possibly surprise some surgeons not present to notice that the contra indications of electricity as contrasted with surgery received marked notice.

The JOURNAL has recognized the importance of these demonstrations of advanced electro-therapeutics from the first, having been the only publication to receive and publish the full proceedings of each meeting, and we take pleasure in announcing the early appearance of the transactions of the recent meeting in forthcoming numbers, together with other contributions from time to time, relating to this interesting field of research.

CHOLERA.

At no time since the introduction of cholera into Europe in 1829, were there so many infected points as at present. This is no doubt owing to the greater facilities of communication, while it is also true the number of cases and the mortality incident to the progress of the disease is not as great as heretofore; the necessary result of greater precaution taken to prevent the spread of the same. Cholera is abating in Russia in the districts where for the last two years it has raged with such fatal results, while at St. Petersburg, the Crimea, and a few ports on the Black Sea it is on the increase and will no doubt continue so for some time. Cases are also reported at Constantinople, and for the first time in Servia. Cairo in Egypt is also said to be infected.

In Galicia and Hungary the disease still prevails, while the epidemic is decreasing at the Danube ports in Roumania, with the exception of Brahljon, where the fresh cases and deaths are about the same as for the last three weeks. There is not much change at Rome, Genoa, Leghorn and Naples. At Budapest there is an increase, also at Vienna. In both Budapest and Vienna, cholera is spreading among the better classes. At New Kellendorf, near Vienna, a man died of cholera, whose illness is said to have been caused by drinking water from the Danube.

A panic has been created at Bilbao in the Bay of Biscay in Spain, by the breaking out of cholera and it is rapidly spreading to the surrounding country. At Bareme, a village of 1,000 inhabitants in the Basses Alps in Southeastern France a very violent outbreak has occurred.

There has been a decided increase at Brest, Quimper and various other places in Western and Northwestern parts of France, with an increase in the number of infected localities. In Belgium, cholera is rapidly spreading in Damperemy, Marchiennes and Aupont, small towns in the province of Hainaut. A workman is reported to have cholera at the Hague. This is the first case. There is not much change in the situation at Berlin or throughout the

German Empire, with the exception of Hamburg. Here the disease has again broken out after an exemption of nearly five months. This is significant, as we may expect a like occurrence elsewhere. It is attributed to a break in the pipes that allowed water from the river Elbe to mix with the pure water. (After so long an exemption the question naturally arises how long may streams be polluted by the cholera poison?) Is it not possible that other causes may have had to do with the fresh outbreak? All the cases and deaths reported were in the suburbs of the city. One case occurred aboard the Rotterdam steamer *Amsdel* which has been lying in the harbor since September 16. It is also reported that cholera has appeared in the military barracks at Eppendorf a suburb on the Alster River. Complaint has been made that the cases were not announced earlier and that the water supply was not all filtered. In consequence of this outbreak the Hamburg-American Steamship Company have decided to dispatch their vessels hereafter from Cuxhaven. Steerage passengers for America will be kept five days under medical control at Cuxhaven before embarking. The stopping of the *Augusta Victoria* at Southampton to await the arrival of a medical inspector from Hamburg, was owing to the fact that one of the crew was suffering from choleraic disease. It is announced that if any cases should occur before reaching the port of New York she is to return to Southampton without making a landing. It is also stated that the water supply of Hamburg has been examined and found to be pure. For the last two weeks deaths by cholera at eight different points in England have been reported, the most serious outbreak being that at Hull. The indications are that the disease is slowly spreading in England, although owing to the care taken no serious outbreaks have occurred. The following cable will explain itself:

LONDON, Sept. 19.—Further questions were asked in the House of Commons to-day regarding the presence of cholera in Great Britain. In reply to these questions the Rt. Hon. Henry Fowler, president of the Local Government Board, stated that, with the exception of three ports on the east coast, all the ports of Great Britain were free from cholera. There was not the slightest reason, he added, to suppose that there was an epidemic of Asiatic cholera in any part of the United Kingdom. No cholera cases had occurred at Southampton. The medical experts attached to the Local Government Board held that there was no danger of infection from a ship that had been out fourteen days from Great Britain, and which had a clean bill of health.

Where from and how did the three ports on the east coast become infected? Was it water-borne or brought by vessels to these places, carrying immigrants from the continent for transshipment by way of Liverpool to the United States? Unless the baggage of the steerage is thoroughly disinfected, might there not be danger, even if the vessel had a clean bill of health and had been out from Great Britain fourteen days? From the foregoing it will be seen that, owing

to the many points of infection and their daily increase, there is still danger of the introduction of cholera into the United States this season. While it is true that, owing to the extraordinary efforts that have been made, we have been so far spared, it is also safe to assume that the present pandemic will continue for the next season in Europe. Why not, then, suspend immigration?

In this connection it will not be out of place to call attention to the announced discovery at Berlin of a new bacillus which is claimed to have more to do with cholera than the comma bacillus of Koch; also to a repetition of PETTENKOFER's and EMMERICH's experiment as follows:

VIESSA, Sept. 20.—In the Institute of Experimental Pathology here, Professors Hasterlik and Stockmayer, four students and others swallowed a quantity of comma bacilli. They suffered no bad effects beyond headache and nausea. Professor Stricker therefore draws the conclusion that the comma bacilli will not cause cholera in the case of strong, healthy subjects.

THE POISON OF RESPIRATION.

Some recent experiments by RAUER, *Untersuchungen über die Giftigkeit der Expirationsluft*, detailed in the *Zeitschrift für Hygiene und Infektionskrankheiten*, tend to deprive the organic matter of respired air of the importance hitherto attached to it as a morbid agent. Carbonic anhydrid has always been recognized as deleterious when present in large percentages in the air which enters the lungs. It is the deadly "after damp" of the mines, and many opportunities unfortunately have been afforded of determining the postmortem appearances in death from the inhalation of this gas. We are, therefore, not surprised to find that RAUER's mice died in an atmosphere in which the carbonic acid produced by the mice themselves amounted to 15.5 per cent. because for every per cent. so produced an equivalent amount of oxygen was used up, thus reducing the available oxygen to 5.5 per cent. Nor are we surprised that they lasted longer but eventually died in a free supply of an atmosphere containing 15.5 per cent. of introduced carbonic acid, although the available oxygen of the mixture was 17.5 per cent. We have, however, been accustomed to regard the relatively small proportion of carbonic acid in the vitiated atmospheres of overcrowded rooms as in itself comparatively harmless, and to consider that its quantitative determination by the sanitary chemists was of interest only as a measure of the associated organic elimination from the lungs, to which the headache and prostration attending the breathing of such air are usually attributed. It is true that R. ANGUS SMITH found .3 per cent. of carbonic acid to enfeeble the heart and quicken the respiration even to gasping. He claimed also that these effects could be detected with even .1 per cent., but as he himself failed to recognize such effects in the .2 per cent. of the soda

water factories, the organic matter of the respired air again assumed importance as the most deleterious of the excreta of respiration.

Now, however, comes RAUER with mice unharmed by the products of respiration, provided the carbonic acid be removed. He considers it proved by his experiments that there is no other poison produced by the breathing of animals than the carbonic acid; that indeed the existence of an organic poison in the air exhaled is impossible, for when the carbonic acid was removed there was no injurious effect, and a mixture of artificially produced carbonic acid had the same effect as that produced by an air of respiration containing the same proportion of carbonic acid. With the exception of this acid there is no gaseous poison liable to be effective in small quantities evolved from men or animals, and the conclusion is reached that men may live in absolute health in rooms with defective ventilation.

Without questioning the accuracy of these experiments we are inclined to offset them with the grand experiment that has been made during the past half century by medical men, sanitarians and philanthropists in increasing the air space and ventilation in prisons, tenements, barracks, emigrant and other ships, and living rooms generally, with the result of banishing the deadly typhus which the accumulated experience of generations recognized as due to the aggregation of human beings in confined and unventilated quarters. RAUER's experiments are interesting, but the other is more convincing.

RIGHT TO MAINTAIN SANITARIUMS WHICH POLLUTE NEIGHBORING STREAMS.

Hospitals and homes for the sick are recognized as lawful institutions, to be fostered and encouraged, and not to be discouraged or repressed. But now comes the novel and important question as to whether one who sinks an artesian well upon his own land, and uses the water to bathe the patients in a sanitarium or hospital erected by him on the premises, is liable to injunction and damages for allowing the water to flow into a stream which is the natural water course of the basin in which the artesian well is situated, the owner being free from negligence or malice, and using all due care in avoiding injury to his neighbor. This was exhaustively considered by the Supreme Court of Indiana in the case of *Barnard v. Shirley*, decided June 6, 1893, reported in the advance sheets of 34 "Northeastern Reporter," 600. No principle of law is better settled, it is said, than that a man has the right to the lawful use and enjoyment of his own property, and that if, in the enjoyment of such right, without negligence or malice, an inconvenience or loss occurs to his neighbor, it is a wrong for which there is no liability. If, in the excavation of his land, he should uncover

a spring of water, salt or fresh, acidulated or sweet, he will certainly not be obliged to cover it again, or to conduct it out of its course, lest the stream, in its natural flow, may reach his neighbor's land. But on the main point involved here, the nearest precedent is found in a mining case, where it was held that in the operation of mining in the ordinary and usual manner, a person may, upon his own lands, lead the water which percolates into his mine into the streams which form the natural drainage of the basin in which the mineral is situate, although the quantity as well as the quality of the water in the stream may thereby be affected. And this doctrine has been adopted by the court in this case, where the contention was that water caused to rise from the earth was polluted in bathing the bodies of diseased persons, having all manner of diseases, including syphilis, which after it had thus become befouled, was caused to be conveyed in a tile ditch underground, to the adjoining lands over which it was made to flow into a natural stream of water running thereon, causing such natural stream of water to become befouled and polluted, thereby exposing the same to the stock pasturing and feeding upon said land where stock was accustomed to run, feed, and pasture, such as milch cows, horses and hogs, which drank the water in its befouled and polluted condition. The court said that the natural right to have the water of a stream descend in its pure state must yield to the equal right of those above. Their use of the stream for the manifold purposes for which they might lawfully use it would tend to render it more or less impure. The water might thus be rendered unfit for many uses for which it had before been suitable; but, so far as that condition may result from reasonable use of the stream in accordance with the common right, the lower riparian proprietor has no remedy. Sewage and waste material may be cast into streams if material injury is not thereby caused. Inconveniences resulting from many causes must be endured by individuals for the general good; otherwise we should have to forego a multitude of the blessings of modern civilization.

Still, when a business is dangerous, unhealthful, or otherwise greatly injurious to a community or to an individual, and it is possible to avoid the injury by a more careful management, or even, if necessary, by a removal to a more secluded or less objectionable place, then the owners of the noxious business will be mulcted in damages, and, if necessary, restrained by the courts. And a man may not carry on a business which poisons the air and renders it unhealthy in a thickly populated neighborhood, and especially in the center of a large city. So establishments which involve danger, as powder mills and certain kinds of manufactories, must seek a secluded place where as few persons may be incon-

venience as possible. Then, is it lawful to build a sanitarium for the cure of the sick or to bathe in the waters those afflicted with disease? It is certainly lawful to do so, continues the court, provided the sanitarium is properly conducted and well managed, so as to do no injury to any person which reasonably and with due care can be avoided. This being true, it follows that those who, with due care, use the water of an artesian well to bathe patients at a sanitarium, the well and sanitarium being on their own premises, are not liable to an adjoining owner for allowing the water, so polluted, to flow into a stream which is the natural water course of that section. Moreover, if the person complaining stood by while money was being expended in erecting such sanitarium, and acquiesced for more than a year in the flow of water, he could not, on account of the law of estoppel, enjoin the continued operation of the sanitarium.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.—Special car for physicians will leave the new Illinois Central R. R. station, 12th Street and Michigan Avenue on Tuesday evening at 11:30, by the "Big 4" route, reaching Indianapolis at 7 A.M. Fare for the round trip, one and one-third excursion rate. The sleeping-car will be at the depot at 9:30 P.M. for such as wish to retire earlier than 11:30. Engage sleeper and buy tickets at the Big Four office, No. 234 Clark Street.

SELECTIONS.

Report of the British Local Government Board, 1891-92.—The supplement to the twenty-first annual report of the Local Government Board, 1891-92, containing the report of the medical officer, has just been received. Dr. R. Thorne Thorne, who now occupies this important position under the British Government, begins his report with a testimonial to the distinguished services of his predecessor, Sir George Buchanan, who resigned March, 1892. "For over thirty years," he says, "Sir George Buchanan has, either as medical inspector or as the Board's medical officer, contributed to the annual reports of the medical department, and many of his contributions have become classic in the literature of public health both in this and in other countries. But those alone who have had the opportunity and pleasure of working under his direction can appreciate to the full the important influence for good which his labors have had; and they alone can realize how much the medical department owes to the example which he set, as an earnest worker and director who never ceased to claim that all true sanitary progress must be based on accurate and scientific research into the etiology of disease." Sir George Buchanan was a worthy successor to Sir John Simon, whose name is a household word in the annals of public health.

An interesting account is given by Dr. Bruce Lowe of an anomalous illness that prevailed in Northamptonshire characterized by pneumonia, sometimes by meningial symptoms, and frequently associated with tonsillitis or sore throat. Certain of these cases had much in common with sporadic cases of cerebro-spinal fever that prevailed in some of the Eastern counties during the previous year.

An outbreak of scarlet fever at Enfield and Edmonton,

investigated by Dr. S. Moreton Copeman, was attributed to a milk supply which was derived from a farm at some distance from Essex, where attacks of the same disease occurred among consumers of milk from the same farm. No infection of the milk from a human source could be made out, but the cows were found to be suffering from udder eruption. Inoculation of calves with matter from this eruption gave negative results in the hands of Dr. Klein.

In cultures on gelatin a non-liquefying microbe was the predominant organism, similar to the streptococcus isolated by him from sores on Hendon cows in 1885, but the present organism inoculated into mice proved only doubtfully pathogenic.

Complaints of nuisance and of injury to health from the transportation of town manure to agricultural districts led to an investigation and an exhaustive report on the subject. The complaints had reference chiefly to manure from London, although that from other large towns as Liverpool, Newcastle, Nottingham, Portsmouth and Plymouth, had also been complained of in the districts to which it is distributed. London manure is as a rule entirely free from human excreta, but it is otherwise a compound of nearly every form of animal and of some forms of vegetable refuse; such materials as dead and putrefying animals, fish-guts, paunches, etc., being mingled with stable manure, cabbage stalks, rotten vegetables, etc. And the diseases which were most commonly regarded as being referable to the offensive emanations were diphtheria and allied sore throat. Two principal objects were held in view during the inquiry. To learn how far allegations as to injury to health and even as to the production of definite diseases were supported by actual experience, and to ascertain how far nuisances, owing to the unloading and temporary deposit of the manure at railway sidings and elsewhere, and lack of care in carting could be dealt with by law or regulations. The outcome of the inquiry under the first heading showed that in so far as bodily discomfort and functional disturbance, at times involving general impairment of health, are concerned, exposure more or less recurring to the offensive effluvia concerned does affect health, and that whilst certain affections, such as sore throat, which it has not always been possible to differentiate from diphtheria, can with some degree of certainty be held to have relationship with exposure to the manure effluvia, it has not been possible so to eliminate other sources of infection and of disease as to identify the effluvia with the production of any specific affection. To a great extent the nuisances arising from the manure traffic are already under the control of local authorities through the provisions of the Public Health Acts or through by-laws which may be made thereunder; but in agricultural districts and small market towns there is often an indisposition on the part of local authorities to exercise the powers which they possess in this connection.

The supplement contains a further report on the pathology and etiology of diphtheria by Dr. Klein. Taking the presence of the Klebs-Loëfer bacillus in definite relation with the mucous membrane as the *casus causa* of diphtheria, he tested various throat ailments with the following results: "Scarlatinal diphtheritis" occurring in the early days of scarlatina is not judged from the bacteriological standpoint, diphtheria; but similar manifestations whether of diphtheritic or croupy type, occurring in the later stages of and during convalescence from scarlet fever, are almost invariably true diphtheria. He found also that membranous croup of the larynx or trachea, although altogether dissociated clinically from diphtheria, must be regarded as essentially that disease.

Dr. Klein's experiments on the inhibitory action of the metabolic products of one microorganism on the life pro-

cesses of pathogenic organisms are full of interest. The expectation that the chemical products of bacillus pyocyaneus would be found to have distinct inhibitory action on the tuberculous process recorded by the medical officer in his report for 1890, has been fully borne out so far as regards guinea pigs by these experiments. Guinea pigs were inoculated, some with material of bovine, some with human tubercle, and as soon as the disease was established certain of the animals were repeatedly injected during successive days, now with dilute, now with undilute sterilized cultures of bacillus pyocyaneus, while others were kept for control. The latter invariably died in the usual time, while in the former the tuberculous process was delayed or even arrested. So uniformly in this way was inhibition of the tuberculous process obtained, especially with undiluted cultures of the bacillus, that further tests were made on cows and calves; but attempts to set up tuberculosis by subcutaneous inoculation of the matter of bovine tuberculosis practically failed in the cows and calves used in the experiments, and so far he has been unable to make further trial of the inhibitory action of the bacillus pyocyaneus.

Dr. Sidney Martin obtained during the year from the blood and spleen of persons dead of diphtheria, from the diphtheritic membrane in cases not fatal, and from artificial cultures of the bacillus diphtheriae albuminosus an organic acid which, when injected into rodents produced definite physiological results of a nature parallel with those observed in the human subject attacked with diphtheria,—particularly did he observe those nerve lesions that have obtained the name of diphtheria paralyses. These lesions are due to a degeneration of the peripheral nerves, which is an early and direct result of the diffusion in the experimental animal of the chemical products of diphtheria and chiefly of the albumoses.

Some interesting observations by Dr. Andrews on pus as a culture medium for certain pathogenic and saprophytic microorganisms are also reported. For the most part the microbes failed to multiply. Among the pathogenic species anthrax and diphtheria were at opposite points; the bacilli and spores of the former died out in the pus, but the bacilli of the latter not only retained their vitality but even multiplied.

The report is illustrated by some fine reproductions from photographs showing the degeneration of the peripheral nerves caused by the intravenous injection of albumoses.

Epidemic Influenza.—In 1891, Sir George Buchanan, the Medical Officer of the Local British Government Board, presented to the Board a report on influenza by Dr. H. F. Parsons. Recently his successor, Dr. R. Thorne, has submitted a further report by Drs. Parsons and Klein on the recurrence of the disease in epidemic form in the spring of 1891 and winter of 1891-92. The onset of these recurrences was less sudden than in the case of the epidemic of 1889-90; and this is regarded as evidence that a severe epidemic may serve to give a certain immunity against another in the same locality. There were, however, some notable exceptions to this, and no condition of site, soil, climate, sanitary circumstances or occupation has yet been instanced as giving a satisfactory explanation of the different incidences.

In 1890 the average death rate from influenza per thousand living was 157; in the later epidemics or recurrences it varied from 52 to 58 in the urban, to 53 in the rural districts, the later having a larger proportion of old people in their population. The mortality was not highest in localities having a high general death rate, nor was it highest in those having a high rate for diseases of the respiratory organs; but there was a distinct parallelism between deaths from influenza and those from diseases of the heart and other organs of the circulation.

Epidemic influenza does not check other epidemics as has sometimes been stated by observers in former times; for during the prevalence of the recent epidemics there were at various places high death rates sustained for several weeks from whooping cough, measles and scarlet fever.

Multiple cases in a household frequently occurred in succession, and the first case could in numerous instances be

traced to exposure to infection from a previous case or a visit to an infected place. In fact, the evidence shows influenza to be propagated from person to person. The disease followed the lines of human intercourse in so many instances that atmospheric causes must be given up in the theory of its propagation. Moreover, the discovery of a bacillus peculiar to the sputa of influenza, not only suggests a personal transmission, but the necessity for dealing with these discharges as is held necessary in the case of discharges from the throat, mouth and nostrils of scarlet fever and diphtheria. Klein verified the observations of Pfeiffer and Kitasato on the constant and copious occurrence in the bronchial secretions, during the acute stage of cases of influenza, of a minute, non-mobile bacillus. The report is illustrated with upwards of forty reproductions of photographic representations of the bacilli. Inoculation into rabbits gave negative results, and the same may be said of similar experiments on monkeys. Horses were not used, but as no disease akin to influenza was observed among the inferior animals during the progress of the epidemics, Klein inclines to the opinion that the disease among horses to which the name of influenza is commonly given can not be identified with influenza in the human subject.

Dr. Caldwell Smith of Anderson College, Glasgow, is cited as follows: "It is to the life history of Pfeiffer's bacillus that we must direct our attention, if we wish to understand the seemingly strange vagaries of the disease. I believe strongly that it is very infectious, and that it is even in the prefebrile or incubation period. An individual is infected by breathing at once the expired air from a person suffering from the disease, and I believe this to be the only method of infection. In this respect it resembles typhus fever. I can not see my way to believe in mediate infection, as the germ can not, according to Kitasato, grow at a temperature lower than 28° C. From my own clinical observation I have rarely met with a case which could not have arisen from a previously existing one, and even in those few rare cases, if strict inquiries had been made, I believe that the source of infection would have been discovered. Again, the bacillus is, I think, easily destroyed by free ventilation. From my own observation I would say that drying does not preserve, but destroys it, and that, like the cholera spirillum, its life history is, though difficult to explain, a very short one. In a suitable medium, that is, in the human body, it must multiply enormously, and in overcrowded apartments it plays havoc with the inmates."

Granted that influenza is propagated by infection from person to person, what are the circumstances which conduce to its epidemic spread at one time, often simultaneously in widely distant places, and not at another? To this question Dr. Parsons answers that it probably depends on the degree of concentration of the specific poison, likening its spread to a fire lighted in green wood, which if small will die out, but if large may set fire to the wood which will continue to burn. "Or we may compare the resisting forces of the human body (be they phagocytes or something else) to a strong man who can vanquish a number of foes one at a time, but would be overpowered by them if they attacked him all at once. A person of ordinary powers of resistance may escape serious harm from a small dose of the influenza poison (whether microbe or its product) but will succumb to a large dose or to a prolonged exposure. The feelings of malaise so commonly felt during an influenza epidemic by persons not actually themselves the subjects of the disease are, we may suppose, the effects of minor doses of the poison."

The notable clinical points observed during the epidemics were the debility left by the attack, the liability to pneumonia to which most of the mortality was due, the gastrointestinal catarrh, cerebro-spinal symptoms and the simulation of scarlet fever by an erythematous rash, desquamation and strawberry tongue. Among the sequelae were noted: great prostration, with confusion and an approach to mental and physical paralysis; neuralgia, persistent dyspepsia, abdominal pains, inflamed throat, rheumatism, phlebitis, meningitis, deafness, peritonitis, pericarditis, excessive prolongation of subnormal temperature, as sometimes observed

after scarlet fever; diarrhea and lastly desquamation of tongue and fauces as in scarlet fever.

The clinical diagnostic marks between ordinary catarrh and mild cases of influenza are not distinctly outlined, the most notable being the greater tendency in influenza to pains in the back and in the course of the spinal nerves, the dental and frontal nerves often being affected. Influenza also is followed by greater and more persisting prostration. But the necessity for clinical diagnostic signs will hereafter be obviated by a demonstration of the specific bacillus.

SOCIETY NEWS.

American Dermatological Association.

Abstract of the Proceedings of the Sixteenth Annual Meeting, held in Milwaukee, Wisconsin, September 5 and 6, 1893.

SEPTEMBER 5—FIRST DAY—MORNING SESSION.

The Association met in the club-room of the Pilester House, and was called to order by the President, Dr. GEORGE HENRY FOX of New York, at 9:30 A.M.

The first paper read was by Dr. R. B. MORISON of Baltimore, Md., entitled

COSMETICS.

The author said that cosmetics, in a general way, may be divided into two classes, namely, those which are irritating, and those which are soothing. For instance, if we wish to remove freckles or warts, a stronger application must be made than if we simply prescribe for a redness following an acne, or an eczema. It is invariably his custom to teach the patient, either through himself or his assistant, how to apply local remedies. Salves, plasters, lotions, and caustics are so often misapplied that experience had taught him to have an application from which one hoped to get the most good, made by skilled hands to begin with. He finds that nothing suits his patients better for the removal of freckles than the following solution:

R. Corrosive sublimate, grs. vii.	48
Distilled water, 5vi.	36
Spirits camphor, 3ss.	16
Rose water, 5v.	20

Three or four thicknesses of linen cut to cover the seat of freckles, are moistened with the solution and placed upon the face at night until they dry, when they are taken off. Whatever remains on the skin is left there till morning and then washed off. After a few nights' application the face becomes red, and the epidermis begins to peel off in fine scales. Then an ointment is used night and morning, the application being made by gently rubbing it over the face, with a clean finger for five minutes at a time.

In the removal of superfluous hairs, the author has given up electrolysis. The results which he had had himself and those which he had seen of others have not been sufficiently good to warrant its continuance. He finds that the proper application of a good depilatory answers the purpose much better. There are many women who wish to get rid of the white lanugo down on their faces, upon whom it seems that electricity can not be used for fear of stimulating the growth of the surrounding hair, and the appearance of permanent scars. If a preparation of yellow sulphate of arsenic and quicklime, of equal parts, made into a paste with hot water, be allowed to dry on the hairy skin it removes the hair for ten to twenty days, and sometimes permanently. On the other hand, nothing seems to take the place of electrolysis where there are a few strong hairs growing from moles, in the removal of moles themselves, in angioma, or in permanent small red spots.

For the removal of warts the author prescribes the following:

R. Hydrarg. bichlor., grs. v.	30
Ac. salicyl., 5i.	4
Collodion, 5i.	32

He sometimes increases the bichloride of mercury to 30 grains in the same amount of collodion, if the milder application does not answer. It is applied every day once, the upper crust of the previous application being removed before a fresh one is made. Four such applications generally soften the wart to such a degree that gentle traction removes it painlessly, the further dressing being any simple ointment.

The author had obtained excellent results in cases of acne by the use of the galvanic current.

Dr. GEORGE T. JACKSON of New York, read a paper entitled

A CASE OF RHINO-SCLEROMA.

in which he said that in October, 1892, he had the pleasure of presenting to his class at the Woman's Medical College of New York Infirmary, a case of rhino-scleroma. There have been only three cases of this disease reported by the members of the American Dermatological Association since its foundation in 1877. The patient, a woman, 54 years of age, was born in Hungary. The disease began sixteen years ago as a slight thickening of the upper lip to the left of, and just under the septum nasi. Since then it has grown slowly and without pain. During the past four years it has increased in size more rapidly than during the preceding twelve years. At present it appears as a hard, well-defined, elevated, old ivory-colored mass located upon the upper lip, beginning at a point a little to the right of the middle line and occupying near the whole of the left side of the lip. It runs up upon the left side of the septum nasi to a slight extent. It is slightly lobulated, so that it has an uneven surface, and shows a number of dilated blood vessels running over it, and a number of white points apparently representing plugged up and dilated follicles. There is no history of syphilis, nor does it look like a syphilitic growth. There is no sign of ulceration nor tendency to break down. She has been previously under the care of Dr. Charles W. Allen of New York city, who had cut out a small piece of the growth, and this had been examined microscopically by Dr. Lustgarten for the bacilli, discovered by Friesch, with negative results on account of the meagerness of the material. Nevertheless, there was no doubt as to the diagnosis.

The disease is a very rare one, and most of the cases have been reported from Austria and southern Russia.

No satisfactory treatment of the disease has been found. The best results so far reported have been attained by the use of salicylic acid injected into the tumor daily, at 1 per cent. solution of the acid or a 2 per cent. solution of salicylate of soda being used; while ten grains of the acid were administered by the mouth three times daily.

A CASE OF CIRCUMSCRIBED SCLERODERMA MORPHOEA.

This was the title of a paper read by Dr. W. T. CORLETT of Cleveland, Ohio. Mary M., aged 10 years, an intelligent looking girl, well nourished, although slightly pale, presented herself, with variously sized and colored lesions on left upper extremity. These were of two years duration. The lesions were located on the extensor surfaces, the most typical lesion being situated in the middle third of the forearm. This was of oblong shape, four inches in length, and two inches in width. It was slightly contracted, lessening somewhat the circumference of the forearm, and was somewhat depressed, resembling cicatricial tissue. The lesion presented a yellowish-brown central area with a slightly uneven surface, slightly indurated, and non-adherent. No anesthesia. Hairs were absent. Outside the central zone was a bluish white area surrounded by a lilac pink border merging into normal skin. Veins about the lesion were very prominent. A second spot had appeared one year after the first on the back of the hand, the characteristics of which were similar to the preceding. During the four months prior to her first visit to Dr. Corlett, seven other spots appeared on the arm and one on the shoulder. These were smaller than the original. Sharp pains were now complained of extending from the shoulder to the hand. These were aggravated by writing, but lasted only a few days. Some itching around the margin of the lesions and occasionally frontal headache were complained of. There was tenderness over the upper dorsal and lower cervical vertebrae; no motor or sensory impairment anywhere, nor were there any other evidences of cord disease. There was no history which might possibly explain the lesions excepting a fall upon the back at the age of five years. No history of nervous or hereditary disease of any kind in the family. The doctor considered the case as a perfect type of morphoea originally, but at the present time the case presents a picture of the atrophic stage of scleroderma.

The points of interest are:

1. The changes of clinical form through which the disease has passed.

2. The predominance of the neurotic element which is so often well marked in morphoea, and which points to the spinal cord as the most probable seat of the disturbance.

3. The confusion of nomenclature of morphoea and its relation to scleroderma is of some interest. Modern treatises on dermatology by American authors are in the main

inclined to consider morphea and scleroderma as distinct affections, while European authorities are rather inclined to the opposite view.

The author has not attempted to advance any original suggestions regarding treatment, contenting himself with the clinical presentation of the case.

Dr. W. A. HARDAWAY of St. Louis, Mo., read a paper entitled

A CASE OF TUBERCULOSIS OF THE SKIN SIMULATING LUPUS ERYTHEMATOSUS.

The patient was a pharmacist, 28 years of age, previous health good, family history good and no history of tubercle. Tall and spare, and of sallow complexion, yet he is a man of great endurance. In May, 1892, he noticed on his left malar region a small yellowish elevation the size of a pinhead. This was supposed to be a flesh worm and was squeezed, blood only being thereby obtained. The lesion gradually enlarged peripherally, becoming hard and red. No subjective phenomena. He came under Dr. Hardaway's care in June, 1892, the lesion being now as large as a dime, presenting an atrophic whitish center surrounded by a slightly raised infiltrated border of a dull red color. The lesion was anesthetic, a characteristic which has been noticed in tubercular syphilides. The anesthesia was temporary. In a short time the patient passed from under observation and was gone for a month, during which time he was thoroughly treated for syphilis by another physician. The treatment simply aggravated the general and local conditions. September 3, 1892, the original lesion was the size of a half dollar, not raised from the surface and moderately infiltrated. The center is still atrophic, and the same narrow dull red line presents at the borders. In a few weeks several small acniform pustules appeared on the right temple, side of the nose, and inferior angle of the right eye. Others presented on the end of the nose, right ala, and left cheek. These lesions were not painful or itchy. Each lesion was surrounded by a red areola which subsequently extended and became infiltrated, crusts forming over the centers of the lesions. The crusts were fatty or sebaceous in character, and with a dull red surface beneath were suggestive of lupus erythematosus. As the borders of the lesions extended the centers cicatrized, presenting the same dirty, yellow appearance of the original patch. December 9, thiosinamin was given hypodermically at 12, and the patient stated that about 7 p.m. the patches became hot and red, remaining so for an hour or two. Other injections of the drug were subsequently given but without effect. December 22, the lesion in the right eye had become as large as a quarter of a dollar. Electrolysis had been tried on the spot on the left temple, but it was still spreading. A new spot was now found on the chest, beginning like an acne papule, which became postulated and finally scaly. This went through the same metamorphosis as the previous lesions, the elevated red border extending until the lesion was as large as a pea, when it was thoroughly destroyed by electrolysis. Early in January a small piece of skin was excised from the lesion on the right temple and examined microscopically. Electrolysis was tried upon the other lesions with an apparent cure, followed by a relapse after a few months, manifesting itself first by the formation of a scale in the center of the scar. Electrolysis was persisted in as fast as the spots appeared and with apparent success. In March a small patch similar to the others appeared upon the scalp; this is now the size of a dime. The tendency to peripheral extension throughout has been a marked feature in this case. The whole nose finally became involved and became a continuous lesion of partly red and partly cicatrized integument, presenting a striking likeness to some forms of lupus erythematosus. Dr. Hardaway thought that this resemblance would have been more striking if the patches on the side of the face had been allowed to coalesce instead of being destroyed by electrolysis. At no time could nodules of lupus vulgaris be demonstrated, nor were the sebaceous plugs of lupus erythematosus seen at any time. The patient's general health has continued so poor that at one time general tuberculosis was considered imminent. A trip to Colorado brought about great improvement. At last accounts the disease was apparently quiescent, the patient's general health good, and no lesions of the lungs and larynx have been detected. Dr. C. Heitzmann reports, after microscopic examination of the excised piece of skin, that a moderate number of tubercle bacilli were found. A large number of inflammatory corpuscles were also detected, displacing the fibrous connective tissue. Nests of inflammatory corpuscles were seen in the arrangement characteristic of

tuberculosis. The diagnosis was local tuberculosis of the skin, which was entirely in accord with the clinical diagnosis.

Dr. H. R. CROCKER of London, Eng., read a paper on LUPUS ERYTHEMATOSUS AS AN IMITATOR OF VARIOUS FORMS OF DERMATITIS.

The author said that lupus erythematosus as an imitator of various forms of simple dermatitis was a formidable rival of syphilis itself. It was to this aspect of the disease that he desired to direct attention by relating some cases and showing drawings which illustrated the points he wished to place before the Association.

The first drawing was an instance of a lupus imitating erythema tuberculatum. The patient was 27 years of age. The lesions commenced on the right cheek. There was only one spot for the first two years, then others formed on the side of the nose, and they then became scattered irregularly over the face, but with the exception of a hemipseed sized nodule on the left ear, there were none anywhere else. The lobes of both ears were atrophied looking, but the patient said there had never been any lesions on them. All the lesions were exactly like an erythema tuberculatum, varying from a hemipseed to half an inch in diameter; quite smooth, except one on the side of the nose, which was scaly. They were of a uniform purplish-red except one, which was whiter in the center.

Case 2 showed an advanced condition of the disease, which began in a similar form to Case 1.

Case 3 was one of lupus erythematosus, like erythema papulatum. The patient, aged 42, was a cab driver. Two years previously he had some rash on the cheeks which lasted only a month, and it was not until a year ago that the present eruption began on the sides of the cheek, and has gradually extended until it reached its present condition. The eruption when seen occupied the whole face below the eyebrows, the orbits themselves and the lower lip escaping, but the chin, except in the center, was affected. On the left side it extended above the brow, but below the orbits, which was remarkably symmetrical. The most recent lesions were on the lower part of the side of the face and below the jaw. In these positions they were the form of erythematosis, slightly raised discs from a half to a quarter of an inch in diameter; the most recent were quite smooth and slightly convex; the larger ones were not prominent in the center and but slightly scaly.

Case 4 was like diffuse erythema, the patient being a lady 43 years of age. The disease had commenced three years previously as a small red spot on the side of the nose and had spread continuously; the whole nose was intensely reddened and slightly scaly, the skin thickened and infiltrated, but the orifices of the sebaceous glands were not patent or plugged.

Another disease which lupus erythematosus imitates is psoriasis, and the author reported a case in point. A rare imitation is that of lichen planus, of which the author had seen only two cases.

Dr. Crocker also reported a case of lupus erythematosus nodulatum. He had met with three or four other cases of this, but not with so many distinct foci of disease. In two cases there was only a single nodule in each. He also remembers a case in which there were even more foci of disease in a patient of the late Dr. Tilbury Fox. Cavaty also showed a man at the Dermatological Society of London, in 1892, but Dr. Crocker was not aware of any other cases having been recorded.

(To be continued.)

New York State Medical Association.—Program of the proceedings of the tenth annual meeting, to be held at the Mott Memorial Hall, on Madison Avenue. Introductory, Monday, October 9, 1893.

Evening Session, 8 o'clock.—1. Address of Welcome, by the chairman of the Committee of Arrangements, J. G. Truax, M.D., of New York Co. 2. Address by the president, B. M. D. Address: The medical work of the Association during its first decade, by John Shrady, M.D., of New York Co. Collection.

First Day, Tuesday, October 10.—Morning session, 9 o'clock. Order of business: a. Calling the meeting to order. b. Address of Report of the Committee of Arrangements. c. Address of the president. Read at evening session October 9. d. Annual report of the council. e. Report of special committees. f. Unfinished business. g. New business. A. Annual reports of the presidents of branch associations, in their numerical

order, to be read by title. *B.* Annual report of the president of the New York County Medical Association, to be read by title.

4. Address: The surgical work of the Association during its first decade, by Stephen Smith, M.D., of New York Co.

5. "Report of eight cases of placenta previa," by Zera J. Lusk, M.D., of Wyoming Co.

6. "Penetrating wound of anterior fossa through orbital plate of frontal bone. Recovery," by Zera J. Lusk, M.D., of Wyoming Co.

7. "The treatment of epithelioma and the canceroid ulcers by topical application," by Nelson J. North, M.D., of Kings Co.

8. "Prevention of disease," by James G. Porteous, of Dutchess Co.

9. Announcement by the presiding officer that the Fellows from the different districts shall appoint two members of the nominating committee from each district. *i.* Appointment by the president of a member at large of the nominating committee. *j.* Adjournment of the session. During this recess of half an hour, the Fellows from the different districts shall meet to appoint the two members of the nominating committee from each district.

First Day, Tuesday, October 10.—Afternoon session, 1 o'clock. Discussion on lesions of the pleura. 9. The discussion will be opened by John Shady, M.D., of New York Co., propounding the following questions:

Question 1. What are the factors of pleurisy? Its forms and contributive conditions? What are the pathological changes in a case of progressive pleurisy ending in recovery? 10. by Frank W. Ross, M.D., of Chemung Co. 11. by William McCollom, M.D., of Kings Co.

Question 2. What are the points of differential diagnosis in pleurisy and other affections of the chest? 12. by Edward F. Brush, M.D., of Westchester Co. 13. by J. Blake White, M.D., of New York Co. 14. by John G. Truax, M.D., of New York Co.

Question 3. What is the treatment of empyema, with relative value of aspiration, rib resection and free opening with tube drainage? 15. by M. K. Hogan, M.D., of New York Co. 16. by Charles A. Leale, M.D., of New York Co.

17. "The surgical treatment of pulmonary cavities," by N. P. Dandridge, M.D., of Cincinnati, O.

First Day, Tuesday, October 10.—Night session, 7:30 o'clock.

18. "Remarks on fermentative dyspepsia," by Austin Flint, M.D., of New York Co.

19. "Open treatment of tuberculous disease of the joints," by T. M. L. Chrystie, M.D., of New York Co.

20. "Bloodless amputation at the hip joint. Report of cases operated on by the author's method," by John A. Wyeth, M.D., of New York Co.

21. "Report of a case of osteotomy of both femora for the relief of deformity following ankylosis of the hip joints," by Reginald H. Sayre, M.D., of New York Co.

Second Day, Wednesday, October 11.—Morning session, 9 o'clock. Order of business: *a.* Calling the meeting to order. *b.* Communications from the council. *c.* Reports of special committees. *d.* Unfinished business. *e.* New business.

22. Address: The obstetrical and gynecological work of the Association during its first decade, by George Tucker Harrison, M.D., of New York Co.

23. "Rare forms of gout and rheumatism," by Sir James A. Grant, of Ottawa, Canada.

24. "Treatment often indicated after trachelorrhaphy," by William H. Robb, M.D., of Montgomery Co.

25. "R," by Henry D. Didama, of Onondaga Co.

26. "Ten years' experience in the treatment of cataract," by Alvin A. Hubbell, M.D., of Erie Co.

27. "The treatment of enteric fever," by Gustavus Eliot, M.D., of New Haven, Conn.

28. "Voluntary commitment of the insane to asylums," by W. D. Granger, M.D., of Westchester Co.

f. Adjournment of the session.

Second Day, Wednesday, October 11.—Afternoon session, 1 o'clock.

29. "Surgical and pathological memoranda," by Donald McLean, M.D., of Detroit, Mich.

Discussion on the treatment of appendicitis. 30. The discussion will be opened by Frederic S. Dennis, M.D., of New York Co., propounding the following questions:

Question 1. What proportion of cases of appendicitis end in resolution?

Question 2. What class of cases require immediate operation?

Question 3. What class of cases do not require immediate operation? These questions will be answered by: 31. R. N.

Cooley, M.D., of Oswego Co. 32. Donald McLean, M.D., of Detroit, Mich. 33. W. S. Tremaine, M.D., of Erie Co. 34. Joseph D. Bryant, M.D., of New York Co. 35. John W. S. Cooley, M.D., of New York Co.

Second Day, Wednesday, October 11.—Evening. Banquet. Fellows of the Association have made arrangements to celebrate this first decennial assembly by a banquet, further notice of which will be given by the Secretary.

Third Day, Thursday, October 12.—Morning session, 6 o'clock.

Order of business: *a.* Calling the meeting to order. *b.* Communications from the council. *c.* Report of the nominating committee, and action upon such report by the Association. *d.* Report of special committees. *e.* Unfinished business. *f.* New business.

36. "The male catheter, with some observations upon the proper mode of introduction into the bladder," by Douglas Ayres, M.D., of Montgomery Co.

37. "Researches on the efficacy of vaccinia after typhoid fever," by William Finder, Jr., M.D., of Rensselaer Co.

38. "Reflections on the need of close observation of disease and upon the value of hygienic therapeutics," by H. Ernst Schmid, M.D., of Westchester Co.

39. Unique case of traumatic tetanus, with generalization recovery," by John G. Truax, M.D., of Broome Co.

40. "A case of puerperal blindness," by Darwin Colvin, M.D., of Wayne Co.

41. "A plea for the non-operative method of treating dysmenorrhea, pelvic inflammation and pelvic abscess," by T. J. McGillivuddy, M.D., of New York Co.

42. "An additional note on nephrotomy and nephrectomy," by E. D. Ferguson, M.D., of Rensselaer Co.

43. "Fifty operations for laceration of the cervix uteri," by J. B. Harvie, M.D., of Rensselaer Co.

44. "Brief comments on the materia medica, pharmacy and therapeutics of the year ending October 1, 1893," by E. H. Squibb, M.D., of Kings Co.

g. Adjournment of session.

Third Day, Thursday, October 12.—Afternoon. Excursion to the island hospitals by invitation of the commissioners of charities and correction. Luncheon will be served on board the steamer, which will start at 1 o'clock from the pier at the foot of 26th Street, East River.

"Papers may be read" — either entire, by abstract, or by title only, as may be determined by the council. —

"The reading of a paper shall not occupy more than thirty minutes, except by permission of the Association."

"No person shall speak more than once, and then not longer than ten minutes, in the discussion of any paper, except by permission of the Association."

"No voluntary communication shall exceed fifteen minutes in length, except by permission of the Association. —"

"See By-Laws, Article N, Sections 7, 8, 9 and 11."

COUNCIL OF THE NEW YORK STATE MEDICAL ASSOCIATION, 1893.—*President*, E. D. Ferguson; *officio members of the committee*: John G. Truax, Chairman; Charles E. Dennis, Secretary; F. A. Baldwin, C. G. Campbell, Alfred L. Carroll, Elvira Denison, A. Palmer Dudley, John E. Erdmann, John W. S. Cooley, George T. Harrison, Charles A. Leale, Owen C. Ludlow, James C. Mackenzie, William McAllister, Johnston McLeod, Valentine Mott, A. D. Ruggles, John Shady, Stephen Smith, E. R. Squibb.

COUNCIL OF THE NEW YORK STATE MEDICAL ASSOCIATION, 1893.—*President*, E. D. Ferguson; *officio members of the committee*: John G. Truax, Chairman; Charles E. Dennis, Secretary; F. A. Baldwin, C. G. Campbell, Alfred L. Carroll, Elvira Denison, A. Palmer Dudley, John E. Erdmann, John W. S. Cooley, George T. Harrison, Charles A. Leale, Owen C. Ludlow, James C. Mackenzie, William McAllister, Johnston McLeod, Valentine Mott, A. D. Ruggles, John Shady, Stephen Smith, E. R. Squibb.

Second of Districts: J. C. Hannan, Vice-President, Hoosick Falls, Rensselaer Co.; Thomas Wilson (1893), Claverack, Columbia Co.; J. B. Harvie (1894), Troy, Rensselaer Co.; E. D. Ferguson, Secretary and Treasurer, Troy, Rensselaer Co.; Charles Albany, Clinton, Columbia, Essex, Green, Rensselaer, Saratoga, Schoenectady, Schottsville, Warren, Washington.

Third of Districts: N. Jacobson, Vice-President, Saratoga, Onondaga Co.; Homer O. Jewett (1893), Cortland, Cortland Co.; M. Cayana (1894), Oneida, Madison Co.; Charles Broome Cayana, Chenango, Chenango, Cortland, Delaware, Madison, Onondaga, Otsego, Schuyler, Seneca, Tioga, Tompkins.

Fourth of Districts: J. L. Link, Vice-President, Warsaw, Wyoming Co.; Thomas D. Strong (1893), Westfield, Chautauque Co.; F. H. Moyer (1894), Moscow, Livingston Co.; J. C. Allegheny, Cattaraugus, Chautauque, Erie, Genesee, Livingston, Monroe, Niagara, Ontario, Orleans, Steuben, Wayne, Wyoming, Yates.

Fifth of Districts: S. R. W. McLeod, President, 217 West 25th St., New York, New York Co.; John G. Truax (1893), 17 East 17th St., New York, New York Co.; Alfred L. Carroll (1894), 30 West 9th St., New York, New York Co.; John W. S. Cooley, Director of the Library, 24 Madison Avenue, New York, New York Co.; John Shady, Member-at-large, 119 West 124th St., New York, New York Co.; J. B. Harvie, Saratoga, New York Co.; Putnam, Rochester, Richmond, Rockland, Suffolk, Sullivan, Ulster, Westchester.

Communications may be addressed to Dr. E. D. Ferguson, Secretary, Troy, N.Y.

Blank applications for membership in the Association, at the Journal office.

Tri-State Medical Society.—Regular session will convene at Peoria, Ill., Tuesday and Wednesday, October 3 and 4, 1893. All members of the regular medical profession are cordially invited to be present and participate with us. W. H. Martin, President; J. M. Ball, Secretary.

Program.—Morning sessions, 9 A. M. Afternoon sessions, 2 P. M. Lecture on Tuesday evening, October 3, at 8 o'clock, by Emory Lanphear, M.D., Ph.D., of Kansas City, Mo. Subject, "The Wonders of the Brain."

The sessions of the Society will be held in the spacious hall of the Y. M. C. A.

Order of Business.—1, Roll call; 2, reading of minutes of last meeting; 3, reading of notes from absentees; 4, proposals for membership; 5, report of committee on credentials; 6, resolutions introducing new business; 7, selection of next place of meeting; 8, report of special committees; 9, report of treasurer; 10, election of delegates to State societies; 11, miscellaneous business; 13, address of the retiring president; 14, reading of essays; 15, election of officers; 16, adjournment.

In Memoriam.—Wesley V. English, M.D. J. A. Scroggs, M.D., Keokuk, Iowa.

List of Papers.

1. Charles W. Hall, Kewanee, Ill., "Epilepsy."
2. J. B. Murphy, Chicago, Ill., "Perforative appendicitis."
3. Wm. Jepson, Sioux City, Iowa, "Intestinal obstruction from a gallstone."
4. John Puntton, Kansas City, Mo. "Treatment and prophylaxis of insanity."
5. E. Wylliss Andrews, Chicago, Ill. "Recent improvements in the surgery of hernia."
6. H. H. Mudd, St. Louis, Mo. "Cancer of the tongue."
7. J. S. Pyle, Canton, Ohio. "A plea for the appropriation of criminals condemned to capital punishment to the experimental physiologist."
8. M. S. Marcy, Peoria, Ill. "Abortion."
9. George Minges, Dubuque, Iowa. "Further Experience with Koch's tuberculin."
10. Boerne Bettman, Chicago, Ill. "Extraction of a piece of steel from the vitreous with a magnet."
11. John I. Skelly, Pekin, Ill. "Symphysectomy."
12. C. E. Ruth, Keokuk, Iowa. "Surgical treatment of meningitis."
13. E. J. Blair, Monmouth, Ill. "Amputation above the hip joint."
14. A. V. L. Prokaw, St. Louis, Mo. "The conservative treatment of uterine myomas by operation."
15. Martin M. Ritter, Chicago, Ill. "Intubation vs. tracheotomy."
16. J. F. Percy, Galesburg, Ill. "Vivisection."
17. John B. Bacon, Chicago, Ill. "A new operation for the cure of stricture of the rectum—with demonstration."
18. O. B. Will, Peoria, Ill. "Bacteriology of the female genital tract."
19. Henry T. Byford, Chicago, Ill. Subject not announced.
20. T. I. Beattie, Kansas City, Mo. "The management of uterine fibroids."
21. Ludwig Hektoen, Chicago, Ill. "Fibroid induration following lobar pneumonia."
22. Geo. N. Kreider, Springfield, Ill. Subject not announced.
23. Bayard Holmes, Chicago, Ill. "Can an adequate system of medical education reduce the annual public expenditures for the education and support of the defective and dependent classes? What would such an education cost, what would it save, and how can it be instituted?"
24. Frank Parsons Norbury, Jacksonville, Ill. "Nervous and mental disorders in women incidental to childbirth."
25. Nicholas Senn, Chicago, Ill. Subject not announced.
26. J. H. Duncan, St. Louis, Mo. "Lupus."
27. Ellen H. Heise, Canton, Ill. Subject not announced.

How to become a Member.—Extract from the Constitution: "Membership in this Society shall be limited to those members of the medical profession who are regular graduates in medicine, and who acknowledge allegiance to the American Medical Association. * * * All applications for membership shall be referred to the Committee on Credentials, and shall be accompanied by a fee of two dollars." Extract from the By-Laws: "Every member of this Society shall pay to the Treasurer the sum of one dollar annually before participating in the business of the meeting."

Speakers.—The medical men of Peoria take this opportunity of cordially inviting you to this meeting.

Officers.—President, Dr. W. H. Martin, Kahoka, Mo.;

Senior V. P., Dr. Calvin Snook, Fairfield Iowa; Junior V. P., Dr. O. F. Pyle, Memphis, Mo.; Treasurer, Dr. H. S. Reese, Wayland, Mo.; Secretary, Dr. J. M. Ball, Keokuk Iowa.

Committee on Arrangements.—Dr. W. R. Allison, Peoria; Dr. J. F. Percy, Galesburg; Dr. Frank Parsons Norbury, Jacksonville.

The Medical Society of the Missouri Valley met at Council Bluffs, Iowa, on Thursday, Sept. 21, 1893, under the presidency of Dr. J. M. Knott of Sioux City. The total membership of this Society has reached 365, and it is in a flourishing condition. Dr. F. S. Thomas of Council Bluffs, is the secretary.

DOMESTIC CORRESPONDENCE.

Mr. Ernest Hart Replies to Dr. Hammond.

To the Editor:—My respect for and my sympathy with the medical profession in America, and my knowledge of their sentiments, forbid me to regard Dr. William A. Hammond as their representative in the defense which he puts forward in the columns of the *New York Medical Journal*, Sept. 16, of the practices of publicity hunting, by newspaper interviews, newspaper portraits and of the use of and traffic in secret preparations, etc. I have in the course of recent travel received personally from many hundreds of prominent and representative physicians in Milwaukee, Washington, Boston, Philadelphia, Chicago, Cincinnati, Detroit, and from all parts of the United States, their cordial congratulations on the tone and substance of the addresses which I had the honor to deliver at Milwaukee and Washington. I have been assured on all hands of the entire sympathy of the great body of the profession in the views therein laid down and discussed. I should have been surprised, however, and perhaps disappointed if they had not elicited some expression of pain and anger from certain quarters. "Let the galled jade wince; the withers" of the great American medical profession are, I am assured, "unwringing." Your correspondent, in an access of ethical agnosticism, assumes that the enumeration of ethical data as to medical conduct was, or could be, a reproval direct or implied to the medical profession of America. That is an unmerited insult which he addresses to his profession, and indicates a view which I apprehend to be special to himself. Let him enjoy the practices which he defends; I do not think he is likely to find much support or sympathy in them from medical men in good standing. His account of the position of the medical men in Great Britain is a parody underscoring of serious notice. So, as to myself, whom he favors with some personal abuse, I have been avowedly the scientific adviser to, but it is untrue that I have ever held any of the stock of the Apollinaris Water Company. As to his other trivialities, I was the guest of the Pan-American Medical Congress, and on entering its headquarters I registered in ceremonious form.

I have no desire to be honored amongst "the Pan-Anglicans," (the "Fat Men of America," and the other objects of lay interest, with whom Dr. Hammond puts medical men on a par, and I do not agree with him that medical men should desire to share with them the honor of newspaper notoriety. I do not believe any details of my medical career have ever appeared in any lay paper.

I suggest that it might be desirable for Dr. Hammond to rely less upon his imagination for his facts, and not to assume to speak for a profession from which he has no sort of mandate, and which would, I am well assured, repudiate, if consulted, both his advocacy and his methods of action and of expression.

I am assured that he utterly misrepresents that profession, both in his statement of principles which he avers to be it, and in his abuse of myself. I am, sir,

Yours faithfully, ERNEST HART.

MISCELLANY.

The Chemical Laboratory of the U. S. Department of Agriculture of the World's Columbian Exposition.—Of interest to medical science is the work and exhibit of the chemical division of the National Department of Agriculture in the Government Building at Jackson Park.

This exhibit occupies a liberal floor space in the northeast corner of the Government Building, and is designed to illustrate the chemical work of the department in its various aspects. The appliances for investigating sugar producing plants are perhaps the most complete of any in the world. Full illustrations are given of the analyses of sugar cane sorghum and sugar beets. Large numbers of beets are daily reaching the laboratory from different parts of the country and are at once analyzed. This part of the exhibit has also been put to good use by the board of awards, several hundred samples of sugars and syrups having been examined for the agricultural jury.

A most interesting exhibit shows how the Darwinian law of natural variation has been utilized in the improvement of a sugar producing plant. In 1858 experiments were commenced by the department on this line. In that year in a plot of sorghum growing in Kansas and submitted to systematic examination, there was found one plant with a phenomenal content of sugar. The seeds of this plant were propagated carefully and the progeny again examined. None of the progeny reached the degree of perfection of the parent, but many plants were produced showing a content of sugar above the average. The best of these was selected for further planting, and this process has been continued up to the present time. From this one parent-head, as a result of these continued selections, a variety of sorghum cane has now been fully established having a sugar making value equal to the best sugar cane of Louisiana. Last year nearly five hundred selections were made from canes which had an average content of nearly 20 per cent. sugar. Illustrations are also given of the same line of work with sugar beets.

Of most interest to the medical profession, however, are the exhibit and work relating to the adulteration of foods. Pure food is an essential to health and every physician is deeply interested in securing to the public immunity from fraud in this direction, of both a financial and hygienic nature. The thesis which is proposed by the exhibit is that all foods exposed for sale should be what their names imply. The exhibit shows how far our American food products fail to meet the fundamental conditions of this proposition. Honey purchased in the open market is shown to have been made quite independent of the mediation of bees, or at most having only enough pure honey to give the required flavor. Coffee beans are exhibited which have been molded from a mixture of meal and molasses. Canned goods kept beautifully green by copper make an important addition to this display of the ingenuity of man, unrestricted by any regard for health.

The results of the work in this line of investigation do not condemn the use of copper in greening peas, but emphasize the justice of the demand that artificially greened goods should carry a label announcing that fact, and stating the character and amount of the added greening material. The same remark may be applied to the data obtained by the work of the chemical division in regard to the use of anti-

septics in the preservation of food. The use of salicylic, salicylic, sulphureous, benzene and boracic acids is common of wide extent, and attention is called to the fact that the medical fraternity and the people should be informed regarding the use of these preservatives. If, then, the patient and his doctor prefer to use such foods, it is a question for them alone; the public has at least done its duty in relation to the matter.

There is by no means unanimity of opinion among hygienists in regard to the effect on the human system of continued small portions of salicylic acid, copper, etc., as they occur in the food. In fact, opinions on such subjects are of little value unless based on actual experiment. At least one thing, however, is certain, viz., that no harm is done in letting the consumer know what he is eating.

Every day a large number of chemists may be found busily studying some of these problems relating to foods, and physicians might spend a profitable hour in examining the character of the work.

Distilled liquors, wines and beers are also analyzed for the jury of awards, and the final distribution of medals will rest largely on the results of these investigations.

One of the very interesting facts of the work is found in the study of the olive oil which are on exhibition. It is claimed by the producers of olive oil in California, that they have a powerful competitor in the cotton oil of our Southern States. Much of this oil, it is asserted, finds its way to France, Italy and Spain and returns to this country under the guise of pure olive oil. The examinations which have been made so far do not afford much comfort to the promoters of that rumor. Even were it true, it is not at all likely that foreign exhibitors would place any such adulterated oil in competition. There is no manner of doubt of the fact that a large proportion of the salad oil purchased in this country has had its origin in Mississippi and Texas, but such oils are not found to any great extent in Jackson Park masquerading as products of the olive.

An important part of the work now in progress in the chemical laboratory consists in the analysis of cereals for the agricultural jury. All those cereals—nearly 1,000 in number which have been adjudged worthy of competition by the jury have been sent to the laboratory for examination. The weight per unit volume is first determined, whence the weight per bushel is calculated. Next, the sample is ground until it all passes a very fine sieve. After the removal by means of a magnet, of any iron dust which may have been mixed with the flour through abrasion of the steel mill, the nutrient value of the sample is determined by analysis. The moisture, ash, oil, fiber, and albuminoids are determined by direct analysis and the starch by difference. On the data thus obtained the food value is calculated. For this purpose the percentage of moisture, ash, and fiber is deducted and the nutrient value calculated on the residue, the relative values of the starch, oil and albuminoids being as 1:2.5:2.5 respectively. On these data and the report of the experts on the commercial value of the samples the awards are made. Space does not permit of a more extended notice of the work of this laboratory in food products. Above have been mentioned only some of the more important of the investigations. But in addition to these, nearly all the food products on exhibition in the Agricultural Building have been subjected to some kind of a chemie examination. It is doubtful whether any other work, not strictly of a medical nature, which is carried on at Jackson Park has a more intimate connection with public health and State hygiene than that of the chemie laboratory.

The work is under the direction of Dr. H. W. Wiley, chief chemist of the Department of Agriculture of Washington. Dr. Wiley is himself a graduate of medicine, and while not

sacrificing the promotion of agriculture in any way his medical training may be allowed some credit for the direction which the investigation in food products has taken.

Fair Emergency Hospital Work.—Cases Cared for by Exposition Doctors and Nurses Since May 1.—While it is one of the most important institutions connected with the Fair little has ever been said about the work of the Emergency Hospital. Under direction of Dr. John E. Owens the department devoted to caring for sick and injured people from the start has performed its duties most admirably. The staff of assistant surgeons is composed of Drs. W. H. Allport, N. R. Zeager, S. C. Plummer, and E. J. Edgerly, with J. L. Hills-mantel and W. C. Roughly as resident physicians, W. H. Gentles, Superintendent of Ambulances, and Miss M. R. Brown of St. Luke's Hospital, head nurse. She has at all times a corps of ten trained nurses under her command. They are changed every month so as to give others an opportunity to see the Fair. These nurses are selected from the best hospitals of New York, Pennsylvania, Massachusetts, Baltimore, Boston, Washington, Chicago, Philadelphia, Toronto, and other large cities. Up to Sept. 16th 13,765 patients had been treated. Out of this number there were twenty deaths, three of them victims of the Cold-Storage fire. The record of cases by months is as follows:

May	2,621
June	2,904
July	3,492
August	3,169
September (16 days)	1,717
Total	13,765

The great number of cases in May is due to the fact that a great many workmen were injured in various ways. The great majority of patients have, so the physicians say, been victims of indigestion, superinduced by irregular eating and change of diet. On hot days prostrations were quite numerous. July 4, with 170 cases, was the biggest day, and Sept. 14, last Thursday, Ohio day, furnished 151 ambulance calls. In May were 315, in June 406, in July 581, and in August 564.

Increase of Alcoholism in Europe.—According to the *Lancet*, June 24, the multiplication of deeds of violence among the Latin peoples of Europe, can be distinctly traced to use of stronger drinks. In Southern and Central Europe the human subject is even more susceptible than the dwellers to the north, to the evil influences of alcoholic intoxicants. Even the nationalities dwelling along the Mediterranean have, from this cause, during the last decade, raised the crimes of bloodshed to a figure quite appalling.

Opening of the Chicago Medical Colleges.—The Rush Medical College and the Chicago Medical College respectively held their opening exercises in Tuesday, Sept. 26. The introductory lecture was given by Dr. Norman Bridge at Rush Medical College, and at the Chicago Medical College by Prof. N. S. Davis.

Editorial Change.—Dr. F. S. Parsons has been appointed editor of the Philadelphia *Times and Register*, to succeed Dr. A. F. Waugh. Dr. Parsons has been for many years a member of the American Medical Association and at the last meeting was secretary of the Section on Diseases of Children.

Coroner of New Orleans.—Dr. G. B. Lawrason has been appointed coroner of New Orleans Parish by Governor Foster, to fill the vacancy caused by the death of Dr. Seeman.

There has been too much microbe hunting in Hamburg and too little attention paid to general sanitation.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from September 16, 1893, to September 22, 1894.

Capt. LOUIS BRYANT, Asst. Surgeon, is granted twenty-three days' leave, to take effect about September 17, 1893.

Major HENRY M. ELDREDGE, Surgeon U. S. A., is granted leave of absence for one month, to take effect about October 1, 1893.

Capt. FRANK E. PRICE, Asst. Surgeon, relieved from duty at Ft. Wadsworth, N. Y., and ordered to report to the commanding officer, Ft. Porter, N. Y., for temporary duty at that post.

Capt. WM. C. SHANNON, Asst. Surgeon, is relieved from duty in the office of the Surgeon General of the Army, and as assistant to the attending surgeon, Washington, and will proceed to New York City, and report in person to the commanding general, Dept. of the East, and report in person to the attending surgeon and examiner of recruits in that city, relieving Capt. GUY L. EDIE, Asst. Surgeon.

Capt. H. S. T. HARRIS, Asst. Surgeon U. S. A., is relieved from duty at Ft. Keogh, Mont., and assigned to duty at Ft. Preble, Me.

Capt. M. W. WOOD, Asst. Surgeon U. S. A., is relieved from duty at Ft. Preble, Me., and assigned to duty in Boston, Mass., as attending surgeon and examiner of recruits.

Capt. FRANCIS J. IVES, Asst. Surgeon, ordered to proceed from Ft. Sheridan, Ill., to Chicago, Ill., and report in person to Capt. LOUIS A. LA GAYNE, Asst. Surgeon, in charge of the medical section of the War Department exhibit, World's Columbian Exposition, for temporary duty.

Capt. GUY L. EDIE, Asst. Surgeon, upon being relieved from duty in New York City by Capt. WILLIAM C. SHANNON, Asst. Surgeon, will proceed to Washington, D. C., and report in person to the attending surgeon for duty in his office.

Capt. WM. G. SPENCER, Asst. Surgeon, is granted six months' extension to sick leave of absence granted in S. O. 108, A. G. O., May 13, 1893.

The Commission of the Surgeon General of the Navy.

From one of the military service papers we learn that a fine specimen of the printer's art has just been turned out by the Government Printing Office, being the commission of Surgeon General J. R. Tryon, U. S. N. The commission is printed on vellum and is a beautiful piece of work. In forwarding commissions to bureau officers care is generally taken that the document is neither folded or rolled, so that the "sheepskin" can be framed without showing wrinkles or deformations. The commission of the Surgeon General will be signed by the President in a few days.

Circular.

The Treasury Department has issued the following:

Unlabeled baggage of steamer passengers, and unlabeled baggage of second cabin passengers from chub in infected ports or places, to be disinfected at the quarantine station for the port of arrival.

TREASURY DEPARTMENT, WASHINGTON, D. C., Sept. 19, 1893.

To quarantine officers of the United States, commissioners of immigration, collectors of customs, steamship agents and others.—Department circular No. 65, May 4, 1893, relating to the labeling of baggage and the issue of inspection cards to steerage and cabin passengers, provides that all baggage of steerage passengers destined for the United States shall be labeled at the port of departure, said label to bear the seal or stamp of the consulate or of the medical officer of the United States serving at the foreign port; also, that the baggage of cabin passengers from chub in infected ports or places shall be likewise labeled. Information has been received that occasionally pieces of baggage arrive without being labeled as above required.

It is hereby directed that any piece of baggage, including hand baggage, belonging to a steerage passenger, not bearing a label as provided for in said circular, shall be disinfected by steam at the quarantine station for the port of arrival; also, that the baggage of second cabin passengers coming from chub in infected ports or places, not bearing a label as provided for in said circular, shall be likewise disinfected by steam at the quarantine station for the port of arrival.

In view of the difficulty of accurately inspecting each piece of baggage while on board ship at the quarantine, commissioners of immigration and custom officers are hereby directed to scrutinize the baggage of immigrants when landed at the immigrant station, and should any piece of baggage, including hand baggage, be discovered to be without a label as above required, they are directed to return the same to the quarantine station, where said baggage shall be disinfected by steam, and properly labeled with a certificate to that effect, before said baggage shall be allowed to pass into the United States.

CHARLES S. HAMLIN, Acting Secretary.
1893. Department No. 111, Marine Hospital Service.

INSANITY IN CHILDREN.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY HARRIET C. B. ALEXANDER, A.B., M.D.

CHICAGO.

FELLOW OF THE CHICAGO ACADEMY OF MEDICINE; FORMERLY ASSISTANT SUPERINTENDENT COOK COUNTY INSANE HOSPITAL.

Moreau (de Tours)¹ with equal force and truth, strikes at the grave psychiatric error involved in the denial by pediatricists, of intellectual, emotional and moral affections of physical origin in the child. Such disordered mental phenomena were explained as immoralities, as eccentricities, or as the result of defective education and training. From the time of the great physician of Cos, instances have been cited reversing these opinions. Not, however, until school over-pressure became a burning question was the subject regarded as a topic of general medical interest. The psychological state of the normal child even is much misunderstood. Meynert,² with exceeding fullness and subtlety, thus outlines the evolution of psychological processes in the child:

Kussmaul has shrewdly indicated certain perceptions and movements common to the fetus in utero, which feeds itself, as it were, by swallowing amniotic fluid. He also indicates that there may be special motives, such as the more stimulating taste of the fluid after occasional depletion into it of the allantois, which induce swallowing. Here, then, there are two alternatives; the fetus swallows or it does not swallow. Fetal consciousness is already presupposed, which would exist, however, under circumstances that give but little opportunity for perception. The newborn infant at once discovers signs by which it distinguishes between one set of perceptions and another. One set of perceptions helps it to define the circumference of its own body; another set belongs to the world beyond it. However obtuse this perception may be, though the child may at first not be able to discriminate between the various impressions of space, still it is certain that the child's perception of its own body circumference is established very early. Among other means by which it learns to distinguish between impressions received from its own body and the outer world are these: contact of a strange finger with its own skin excites but one tactile sensation; contact between two parts of its own body excites two tactile sensations; one from the touching, the other from the touched part. Furthermore, a number of strange auditory sensations strike the ear of a child, but only the sound of its own voice is accompanied with muscular sensations, and so the attendant muscular sensations help the child to discriminate between movements of its own body and any other movement it

may see. There is no order of movements, which, under the cover of instinct, can be pushed in between conscious and reflex movements. The first instinct of a child would be the instinct for food, but the origin of that has been discussed. There is absolutely nothing in the sensation of hunger which would acquaint the child with the means of remedying this pain. It obtains naught but the concept of pain. In the general restlessness it displays and in the convulsions ultimately resulting from anemia there is nothing which could be likened to an instinct for food. If the child has not to depend on its own resources but has a nipple put into its mouth then the sensation thus excited starts the reflex mechanism of sucking. The child has thus acquired the concept that the sensation of satiation is connected with the act of sucking, and these two sensory memories are associated with the innervation sensation aroused by sucking, and probably by the scent of the mother's breast. That a child should suck at every finger may be attributable to a reflex mechanism, but the sucking of the child in dreams proves that the act of sucking has produced images which have been registered in the cortex. The factors of this primary abstract ego are not definitely defined. . . . The nature of the ego does not depend upon any definite order of memories, but is determined simply by the most firmly fixed memories. . . . As soon as movements of aggression have taught the child to take hold of things it is evidently under the impression that it is living in a world of sweets; it takes everything to the mouth and licks it. A later aggressive movement—kissing—like the first sucking movements, is probably based upon the act of bringing an attractive object to the mouth. This latter movement is clearly dependent upon a powerful secondary presentation aroused by its impressions, just as the sucking movements during sleep denote secondary presentations excited in the course of dreams. . . . Space vision in the child excites movements of aggression which aim at the possession of the thing it sees, but as it lacks the power of locomotion it has no conception of distance. These aggressive reflexes of the upper extremities are no more coordinated in space than the movements of the eyes are before the child has learned to see, and through irradiation these movements become general, leading to a tossing of the whole body, to kicking with all fours and to cutting of grimaces. These movements though extravagant are not spasmodic, but must be regarded as results of cortical impulses interfered with by cortical irradiation. The acoustic nerve also takes part in reflex impulses; the child that hears others speak or perceives other sounds and noises has the desire to bring forth the same sounds and noises. As its cortical functions improve, it develops the secondary idea that the sounds which it brings forth are similar to

¹ *Pollie chez les Enfants.*

² "Psychiatry," Sachs' Translation.

those of ordinary speech. Wundt correctly remarks that the speech of animals consists of so-called sensory sounds, and this is true of children before they have acquired the faculty of imitating syllables. In all aggressive movements the child over-estimates the possibilities of its powers. Experience and an improvement of the power of imitation correct these false conclusions. As soon as the child has reached that age when all cortical fibers acquire their white substance, purely reflex movements and those due to irradiation diminish in number. In the child the expression of emotion may vary much. Under the influence of the apnetic effect of functional hyperemia attendant upon pleasurable emotions, there will be movements of aggression bespeaking the force of the child's own personality, or there will be spasmodic movements of repulsion (due to irradiation) such as screaming and crying. All these expression movements, whether due to irradiation or not, dispatch sensations of innervation to the cortex, which sensations are there turned into "special memories" and serve later on as impulses, starting the entire groups of movements which are involved in expression. Consequently, these movements of expression result primarily from stimulation of sub-cortical centers, just as simple forms of reflex movements serve as the foundation upon which the structure of more complex, conscious movements is raised. As soon, however, as these irradiatory impulses, which excite the mechanism of expression, are put under control of an organ of motor coördination, they acquire secondarily a higher value as psychological factors of expression. In the child, pleasurable emotions result in general movements of the entire body. Even in the adult, who dances for joy or performs other extravagant movements, occurs a repetition of these primitive mimical movements of the child. A state of excessive pleasurable emotions may pass into a condition of maniacal excitement as a result of dilatation of the arterial network of the brain, or a state of pleasurable confusion may end in a transitory swoon. The doctrine that ideas are inherited and are not the result of perception and association, that movements, even mimical ones, are the result of innate motives and have nothing to do with imitation and early reflexes can hardly be applied to man. Not even the upright gait is innate; it is acquired with difficulty only through imitation and cortical coördination.

Dickson has found insanity in children characterized by subacute maniacal symptoms, garrulity or loquacity, or melancholic depression associated with homicidal or suicidal tendencies. The children are often bright, but irritable and wayward.

As Perez has shown, anger appears very early in children. In the first two months the child shows by movements of its eyelids and hands strong anger when the attempt is made to bathe it or to take something from it.

According to Feneelon, jealousy is much more violent in children than is usually suspected. Bourdin claims that all infants are liars. He, however, ignores the fact that the weak inhibitions of the child prevent it from distinguishing clearly between the subjective and the objective—between its wishes and facts. This condition is essentially one of mental instability and underlies the mental states at the foundation of terror and suspicion. As might be expected, cruelty is very frequent in childhood. Not

from an innate tendency to cruelty *per se* as claimed by La Fontaine and Montaigne, but, because as has been shown by Meynert, the feeble secondary "ego" does not so dominate the primary "ego" as to enable it to recognize the feelings of others. In certain cases this secondary "ego" is not developed, because of inherited, congenital or acquired defect or perverted training.

Motor explosions, for reasons already pointed out by Meynert, readily occur in children, whence the fact noted by Dr. Grace Peckham Murray³ that neuroses in children tend to be motor rather than sensory, since the reflex arcs of which the motor strands form a part are earliest perfected, so that when a sensory stimulus sets free a nerve energy it is likely to overflow into motor paths. Intellectual comprehension of sensation, and consequently of pain is the last to be developed; in consequence, severe nervous shocks which would give rise to exquisite pain in the adult, result in a motor neurosis in the child.

Motor neuroses, as already stated, readily pass into the motor expressions of psychological disturbance; and from these psychological disturbances intensified by the feeble power of discriminating between the subjective and objective, result the hallucinations so frequently noted in children.

The disturbance of the feeble ego results in the appearance in the mental foreground of the child, of cruelty, mendacity, and other primitive instincts. Abulic speech, as Dr. J. H. Kellogg has shown, may occur in the instinctive insanities of childhood from morbid tendencies to commit improprieties of speech. (*American Journal of Insanity*, 1892.)

The child, therefore, gradually acquires a series of checks on its explosive tendencies and the egotism shown in the over estimate of the possibilities of its powers. These elements underlie the mental state of childhood, which, according to Moreau (de Tours)¹ is characterized by an absence of reflection and self-control, by spontaneous and capricious actions, by dominance of immediate sensory impressions and absence of regard for the future, by desire for power and tyrannical use of it. In a study of these phenomena, classification becomes a necessity and the following modified from Moreau (de Tours), is an excellent basis for such study, especially if it be remembered that even the "pure neuroses" in childhood are often attended by mental symptoms. The classification of the psychoses is based on Spitzka.

Neuroses.	Convulsions.		
	Nervous laughs.		
	Nervous coughs.		
	Hiccough.		
	Stuttering.		
	Neuralgias.		
	Hysteria.		
	Hysteria.		
	Chorea.		
	Epilepsy.		
	Somnambulism.		
	Hallucinations.		
	Anomalies of character.		
	Aberrant sentiments.	Love.	
		Jealousy.	
		Anger.	
Psychic Types.	Imperative conceptions.	Purely attended by impulsive acts.	Arson.
			Suicide.
	Idiocy.		Violence.
	Imbecility.		Homicide.
	Night terrors.		Alcoholism.
	Mania.		Theft.
	Acute confusional insanity.		Rape.
	Melancholia.		Non-criminal acts.
	Transitory frenzy.		
	Stuporous insanity.		
	Katatonia.		
	Paranoia.		
	Periodical insanity and hebephrenia.		

The imperfect coordination of the slowly acquired inhibitions is readily upset, whence occur states of uncertainty and resultant terror. "Night terrors" were the earliest morbid mental phenomena noticed in children. "Pavor nocturnus" described by Hippocrates was worthy the clinical insight of the great physician of Cos. The emotion of fear, as Meynert has shown, characterized by greater excitement and attention, is probably the neurosis of a subcortical center (of the medulla) which defies cortical inhibition. Movements of flight may therefore be started by allied associations in the absence of real danger, and even against the will this underlies the conditions found in "night terrors" and explains the running which so frequently precedes epilepsy in children; the so-called *epilepsia cursiva*. The motor elements in childhood's neuroses are therefore not so pure as they at first seem. The sensory inhibitions which enabled the child to determine its own movements from those of others remain dormant, it is true, to spring to the surface in constitutional disorder, not as inhibitions but as sensory accessories.

Among the earliest manifestations of morbid mental activity in children are hallucinations which depend on already registered perceptions. Hallucinations of all the senses may occur, but those of sight are most frequent; next, those of hearing, while taste and smell but exceptionally occur. These hallucinations are readily excited by simple causes, like indigestion, and are present in night terrors which are an intensification of the hypnagogic hallucinations that occur in many adults on awakening. In many instances even moral agencies produce sudden explosions of mental disorder.

The inherited tendencies of childhood predispose to these attacks. As Clouston has shown, neuroses and psychoses not requiring hospital treatment are by no means uncommon in the "too sensitive" child with hereditary taint. Children of this class take "crying fits" and miserable periods on slight or no provocation. These tendencies are aggravated by the results produced by the maternal mental state. The silly threats of mothers often cause such brief attacks. He has seen a boy of five become intensely depressed, cry and moan for hours because of the "hell" which his mother described as the portion of bad boys who tore their pinafores, sinned against God, and disobeyed their mamma.

In predisposed children, subjective frights and unpleasant dreams originate persistent anxieties and hebétude. In such children, precocity, over-sensitiveness, unhealthy strictness in morals and religion for a child, a too vivid imagination, want of courage, thinness and craving for animal food are common characteristics. These children are over-sensitive, over-imaginative, and too fearful to be physiologically truthful, and tend, under fostering, to be unhealthfully religious, precociously intellectual, sensuously artistic, and hypertheoretically conscientious. He points out that what he calls "delirium of young children" is relatively frequent. "In most cases it is a pure delirium, without consciousness, attention, or memory, but in some instances there are frightful hallucinations. In others, an excited melancholia of short duration." "The same children who suffer from delirium at low temperature are those subject to 'night terrors' chorea, epilepsy, hysteria, and

even adolescent insanity (hebephrenia) at later ages."

Krafft-Ebing state that "night terrors" are peculiarly frequent in neuropathic children.

Dreams, somnambulism, and night terrors, according to C. P. Putnam, find their explanation in a loss of the higher and exaltation of some of the lower cerebral functions. The conscious life of the individual is in the realm of the higher functions, which exercise an inhibitory influence on the low.

Steiner² believes that of the immediate causes of "night terrors" and the resultant states, the most important are a bad mental training, ghost description ere retiring, and going to bed in the dark, all of which are calculated to stimulate the lively intelligence of children already timid and excitable.

In regard to the frequency, etiology and types of the various psychoses and neuroses much variance of opinion exists. The frequency with which chorea occurred among degenerates led to an expression of opinion that all choreic children were morally imbecile. The question will, therefore, naturally arise as to the existence of degeneracy in the family of a given child. "Degeneracy," according to Morel³ the apostle of the doctrine, "is the result of a morbid influence, physical or moral. An essential characteristic of degeneracy is hereditary transmission, but of a grave type and more far reaching in consequence than ordinary heredity." This factor plays an exceedingly important rôle in the disorders of childhood. In infancy, are born errors and prejudices almost never uprooted, above all credulity. Although impressions are mobile, still something remains therefrom for the future. The child is dominated by the most pressing appetite and instability resembling that of the ape (as described by Milne-Edwards), or the hysteric is in the main uppermost in childhood. Cabanis has shown that there is no moral distinction between the psychic life of the sexes in childhood at the outset. Upon the power of acquiring checks, turns the after-life of the child and this power is lessened by the cortical deficiencies due to degeneracy which also creates the predispositions to which reference has already been made. Under "insane diathesis" or "insane temperament" has been placed a congenital predisposition most graphically portrayed by Dr. C. F. Folsom:⁴

"It is closely allied to insanity and the neuroses, and at the critical periods of life is exceedingly apt to develop into one of them. It is congenital or due to early interference with normal brain development. It shows itself in childhood and infancy by irregularity or disturbed sleep, irritability, apprehension, strange ideas, great sensitiveness to external impressions, high temperature, delirium or convulsions from slight causes, disagreeable dreams and visions, romantic, intense feeling, periodic headache, muscular twitching, capricious appetite and great intolerance of stimulants and narcotics. At puberty developmental anomalies are often observed in girls and not seldom perverted sexual instincts in both sexes. During adolescence there are often excessive shyness or bravado, always introspection and self-consciousness and sometimes abeyance or absence of the sexual instinct which, however, is frequently of extraordinary intensity. The initiative and imaginative faculties may be quick. The affections or emotions are strong. Velocement dislikes are formed and intense personal attachments result in extraordinary friendships which not seldom swing around suddenly into bitter enmity or indifference. The passions are unduly a force in the character which is said to lack will-power. The individual's higher brain centers are not well inhibited and he dashes about like a ship without a rudder.

fairly well if the winds be fair and the seas calm, but dependent on the elements for the character and time of the final wreck. Invention, poetry, music, artistic taste, philanthropy, intensity and originality are sometimes of a high order among these persons but desultory, half finished work and shiftness are much more common. With many of them concentrated, sustained effort is impossible and attempts to keep them to it impossible. Their common sense, perception of the relations of life, executive or business faculty and judgment are seldom well developed. The memory is now and then phenomenal. They are apt to be self-conscious, egotistic, suspicious, and morbidly conscientious. They easily become victims of insomnia, neurasthenia, hypochondriacal, neurotic, hysterical or insane, and they offend against the proprieties of life or commit crimes with less cause or provocation than other persons.

At the same time that many of them are among the most gifted and attractive people in their community, the majority are otherwise and possess an uncommon capacity for making fools of themselves, being a nuisance to their friends and of little use to the world. . . . If such children could be placed in the hands of judicious and experienced physicians much better results could be obtained and the downward tendency might be stopped."

Among those beings termed by him the "neurotics" Dr. E. S. Talbot¹⁰ has found anomalies of the jaws and teeth exceedingly frequent. Such stigmata of degeneracy were to be expected. The "lithemic" child, of pediatricists, belongs but too often to this class, the lithemia being an expression of degeneracy. Here, also, very often belong the infant prodigies like the two-year-old negro calculator described by Dr. S. V. Clevenger,¹¹ and the host cited by Moreau de Tours. Such precocity is a mental stigmata and, like early puberty appears so often among the degenerate as to give rise to the proverb, "a wit often is a fool at thirty." Shelley is an excellent instance of this "insane temperament."

He was somnambulist from his sixth year.¹² From "very early childhood" he was an imaginative and restless child. Trifles unnoticed by most children, seem to have made keen and permanent impressions upon him—the sound of wind, the leafy whisper of trees, running waters. The imaginative faculties came so early into play that the unconscious desire to create, resulted in the invention of weird tales of legendary creatures, tales sometimes based on remote fact, in attempted delusion of neighbors and in the experience of more or less positive hallucinations. His memory surprised many of his friends. He delighted in "weird and somber tales of the supernatural and horrible." He was extremely desultory and careless in all his habits. His room was a chaos of scientific instruments, chemicals and books. "From thinking the best of friends and acquaintances he could of a sudden, and with insufficient cause, pass over to the other side and think the worst." Like all neuropathies he was easily hypnotized. He was a great hypochondriac. On one occasion, meeting a woman with large legs he was seized by the notion that she had elephantiasis and had infected him. Medical examination demonstrated the falsity of this notion but it persisted for several days. "One evening he actually arrested the dancing of a line of pretty girls, proceeding to examine their arms and necks, with such woebegone gravity that they were terrified and their angry partners silent." He suffered frequently from the topalgias so frequent in neurasthenics and hypochondriacs. His flagrant violations of social conventionalities were notorious. Many of these, however, had, as Symonds has shown, logical bases from the Shelleyan standpoint of reaction against social tyranny not unnatural to a mind early subjected to the brutal "fagging" of English schoolboys and brutality of schoolmasters who found a "voluptuous ecstasy" in flogging boys ere entering on the "feast of reason, flow of soul" of a banquet whereat the flogger was the "genial, humorous" host. Shelley, however, violated his own code in a most capricious manner. An avowed atheist, he took the sacrament in a blatantly audacious manner for interested reasons. He reverted to fetishism and argued for the existence of ghosts. He denounced

legal marriage, but, married Harriet twice; once by the simple Scotch common-law and once by the English church rite. The constant nagging of his intriguing "sister-in-law" which drove Harriet into "nerves" and him into home hatred, led to the estrangement of wife and husband. The hysterical insensibility of the wife to her own children fostered this. Shelley's temperament, however, aided this tendency. He "took strange caprices, unfounded frights, vain apprehensions and panic terrors, and therefore absented himself from formal and sacred engagements." In a month after the English marriage he deserted Harriet and her unborn child, to elope with Mary Godwin. Even Symonds, the most logically psychological of Shelley's analysts, fails to justify this act from Shelleyan principles. In Shelley's case hereditary degeneracy existed. He normally reacted against school tyranny, hence it alone does not account for the defects and peculiarities of his career.

School training, however, may develop very similar states and wreck many a nervous system. Such an acquired predisposition is singularly well illustrated in the lives of Margaret Fuller and George Eliot. Margaret Fuller says:¹³

"My father instructed me himself. At the outset he made one great mistake, more common, it is hoped, in the last generation than the warnings of physiologists will permit it to be in the next. He thought to gain time by bringing forward the intellect as early as possible. Thus I had tasks given me as many and various as the hours would allow, and on subjects beyond my age, with the additional disadvantage of reciting to him in the evening after he returned from his office. As he was subject to many interruptions, I was often kept up until very late, and as he was a very severe teacher, both from his habits of thought and his ambition for me, my feelings were kept on the stretch till the recitations were over. Thus it frequently happened that I was sent to bed several hours too late, with nerves unnaturally stimulated. The consequence was a premature development of the brain that made me an 'infant prodigy,' by day and by night a victim of spectral illusions, nightmare and somnambulism, which at the time prevented the harmonious development of my bodily powers and checked my growth, while later they induced continual headache, weakness and nervous affections of all kinds. As these, again, reacted on the brain, giving undue force to every thought and every feeling, there was finally produced a state of being both too active and too intense, which wasted my constitution and will bring me—even although I have learned to understand and regulate my now morbid temperament—to a premature grave. . . . No one knew why this child, already kept up so late, was still unwilling to retire. My aunts cried, 'Out upon the spoiled child; the most unreasonable child that ever was—if brother could but open his eyes to see it—who was never willing to go to bed.' They did not know that, soon as the light was taken away, she seemed to see colossal faces slowly advancing toward her, the eyes dilating and each feature swelling loathsome as they came, till at last, when they were about to close upon her, she started up with a shriek which drove them away, but only to return when she lay down again. They did not know that when at last she went to sleep, it was to dream of horse-trampling over her, and to awake once more in fright; or (as she had just read in her Virgil) of being among trees that dripped with blood, while she walked, and walked, and could not get out, while the blood became a pool and plashed over her feet, and rose higher and higher till soon she dreamed it would reach her lips. No wonder the child rose and walked in her sleep, moaning, all over the house; till once, when they heard her and came and waked her, and she told what she had dreamed, her father sharply bid her leave off thinking of such nonsense or she would be crazy; never knowing that he himself was the cause of all these horrors of the night."

To these influences Emerson¹⁴ rightly referred her later demonology, with its curious superstition and imperative conceptions. He says:

"Her childhood was full of presentiments. She was then a somnambulist. She was subject to attacks of delirium, and later perceived she had spectral illusion. When she was 12 she had a determination of blood to the head. 'My parents,' she said, 'were much mortified to see the fineness of my com-

plexion destroyed. My own sanity was severely wounded, but I recovered and made up my mind to be a traitor, though ugly." She was all her lifetime the victim of disease and pain. She read and wrote in bed, and believed that she could understand anything better when she was ill. She acted like a girdle to give tension to her feelings. A girl who was with her through an attack of nervous headache which made Margaret totally helpless, assured me that "Margaret was yet in the finest vein of humor, and that those who were assisting her in a strange, painful exchange between laughing and crying, by perpetual brilliant sallies. There were other peculiarities of habit and person. When she turned her head on one side she alleged she had second sight, like St. Francis. These traits and predispositions made her a willing listener to all the uncertain senes of mesmerism and its golden brood which have been ripe of late years" (1889). She had a feeling she ought to have been a man, and said of herself: "A man's ambition with a woman's heart is an evil lot." In some verses which she wrote "To the Moon" occur these lines:

"But if I steadfast gaze upon thy face,

A human secret like my own I trace,

For through the woman's smile looks the male eye!"

And she found something of true portraiture in a disagreeable novel of Balzac, "Le Livre Mystique" in which an equivocal figure exerts alternately a masculine and a feminine influence on the characters of the plot.

The same tendencies are demonstrable in George Eliot. Strongly skeptical and virile in type as was the intellect of George Eliot, her childhood was marked by phenomena of like causation to those already described in Margaret Fuller. Like Margaret Fuller she had a father of "extraordinary determination of character." Her mother was a "woman with an unusual amount of force" but of "ailing habit." George Eliot during childhood "suffered from a low general state of health and great susceptibility to terror at night," and the liability "to have all her soul become a quivering fear" remained during life. She suffered from periodical depression which later gave place to migrainé evidently of uric acid type, and often attended with rheumatoid phenomena. She was "an awkward girl, reserved and serious far beyond her years, but observant and addicted to the habit of sitting in corners and watching her elders." Fear of the unknown in children, seemingly a reversion to the fear of the unknown of savages, tends like it to produce occult belief. This has been pointed out by Emerson in the case of Margaret Fuller. Despite the German rationalism of George Eliot, such fear found utterance in her "Beyond the Veil," a mystically occult contrast with her novels and with the Positivism which was her religion. The philosophy of George Eliot should theoretically have effaced such mysticism, yet, as a survival of "night terrors," it came to the surface.

Dickens teaches a lesson in school training eminently worthy of study when, in discussing the model school in "Hard Times," he says about the teacher:

"Ah! rather overdone, Mr. Choakumchild! If he had only learned a little less, how infinitely better he might have been taught much more. He went to work in the preparatory lessons not unlike Morgiana in the 'Forty Thieves'—looking into all the vessels before him, one after another, to see what they contain. Say, Mr. Choakumchild, when from thy boiling store thou shalt fill each jar brimfull by-and-by, dost thou think that thou wilt always kill outright the robber Fancy lurking within, or sometimes only maim and distort him?"

The career of the modelly trained moral imbecile, "Gradgrind," is an apt illustration of the results of this system. His case is one of the extreme results of school over pressure in which the struggle for marks before maturity more than equals in fierceness and intensity the struggle for good after it. In certain respects this school over pressure checks even in well developed minds the transition from the terror of the unknown of childhood into the calmness of maturity. Many morbid fears, imperative conceptions and acts, which torture the individual during an otherwise healthy career, unquestionably originate in the earlier periods of life.

The treatment of the degenerate offspring of degenerate parents is one of the most serious problems

which confront the pediatrician. Although the parents may be convinced of the necessity of the institution in the rearing of the child, the parents' emotions are too weak to carry out the training decided upon. Incomplete separation of the child of over accomplishment, something of a child of the weak inhibitions of the degenerate, the latter course is practically impossible. Parents who are excessively fond of the children, who are in a certain fashion, and their egoism causes them to think themselves model mothers. I have had such a mother consent to turn over entirely the training of her child to a person recommended by me, and yet at the first attempt of the companion to exercise authority over the child, the mother told the child to do as it pleased. These children need a nourishing, stimulating diet, an outdoor life, regular hours and regular employment; in fact, they require the very life which is led by the healthy children of healthy parents, but which they rarely get unless one of the parents happens to be of sound mind and strong will and financially circumstanced to control the surroundings of the children.

Dr. W. S. Christopher, in a paper recently read before the Chicago Academy of Medicine, has laid stress on the nutritional influences, active in the production of neuroses underlying psychic states, and these deserve more attention than they have received.

Beside hereditary and the other predisposing causes cited already, Dr. Welt very correctly has said that the etiological factors in the production of mental disturbances in children are injuries of the head, either during parturition or later; acute cerebral trouble and abnormal development of the brain; fright, masturbation and infectious diseases may act as predisposing elements. Among the chief exciting causes are the fevers.

There has shown that psychoses following acute diseases are of two classes: the first is met with during the development and the duration of the acute process itself, while the second class is found only during convalescence, or at least during an intermission of the disease. The etiology, as well as the course and the issue in these two groups—the febrile and asthenic deliria—differ considerably.

Kraepelin points out that in pathology of the febrile deliria the exciting cause prevails considerably over the predisposition; the causes of the disease are dependent upon somatic disturbances. Hence the monotony of the febrile deliria, the short course, and the nearly always favorable issue with the disappearance of the etiological cause; on the other hand, the predisposition of the individual forms the most important factor in the development of the asthenic form. The lowered state of the system, depressed by the preceding fever and infection, exhibits itself more when the circulation is retarded during the decline of the fever; and the brain which may have suffered in its vitality by the preceding rise of temperature, is the first organ that reacts on the inadequate supply of blood; besides, there may be an influence of the infectious elements upon the central nervous system, either by affecting the ganglionic cells, or indirectly through a change of the blood by the microorganisms. In the deranged equilibrium of the system even slight irritating influences, afforded by the events of daily life and

frequently overlooked, may cause mental disturbances. In their course the asthenic psychoses resemble the mental derangements of spontaneous origin, and usually terminate in full recovery; with convalescence and better nutrition brain morbidity disappears. Dr. Sarah Welt advises that as a matter of prophylaxis, children after acute diseases, especially when in an anemic and poor condition, ought not to be allowed to leave the bed too early, and the action of the heart should be carefully controlled. Threatening spells of weakness ought to be prevented by administration of good nourishment and stimulants. In occurrence of deliria strict control of the patient becomes necessary; bed rest and a generous administration of alcoholics and heart stimulants. Against the irritable state of the brain, sedatives in result-giving doses should be used.

Dr. Kiernan states that the psychical manifestations of the febrile stage of any disorder are usually an hallucinatory delirium or acute confusional insanity. These may be agreeable in type. With a fall in temperature occur asthenic psychoses, characterized by visual and auditory hallucinations and their consequences. These are due to acute exhaustion of the nerve-centers succeeding to considerable thermic oscillations. The mental symptoms of the febrile stage may aggregate temperature oscillations and in turn be aggravated.

Spitzka¹⁷ finds that febrile and other acute disorders sometimes cause serious and incurable insanity usually combined with more or less arrest of development. This result is most apt to follow when some moral cause, such as a shock is super-added. From 10 to 30 per cent. of infantile insanity is attributable to the acute diseases of childhood, the overwhelming majority being sequelæ of the exanthemata (excluding cases followed by simple imbecility). Scarletina, measles, typhoid and acute articular rheumatism are most to be dreaded in reference to their immediate mental sequelæ. Typhoid is especially deleterious. Naso classifies the febrile insanities according to their period of development: *a*, coincident with the fever as to time and ranging from delirium to insanity; *b*, developing as an apparent aphasia and dementia. Spitzka found but 7 per cent. of his cases attributable to these causes. This low percentage was due to the fact that he did not include fatal cases nor ephemeral deliria, which in children, as Hughes and McBride¹⁸ have shown, replace malarial attacks and which are benign, self-limiting and not apt to come under alienistic care, like the more serious and protracted mental complications which may attain pseudo-cretinism. Aside from an infrequent hallucinatory delirium, there is a continuation of the specific somatic disorder, so that a true convalescence can not be said to have existed. This is often associated with hyperthermia; *c*, developing during convalescence. These last, Spitzka¹⁹ is of opinion, are different from the other two, are probably more benign and are anemic or adynamic. Spitzka states that sudden changes of temperature uncomplicated by other causes can produce transitory frenzy and acute delirious states. This is equally true of the extremes of temperature. Over exposure to the sun and pressure of the unprotected head of an infant to a hot stove have been declared responsible for the

same acute delirious or furious outbreaks that Reich observed in children who, after long exposure to severe cold, suddenly entered a warm room.

Rapid cure of a maniacal delirium after the expulsion of ascarides in several cases proves, in Spitzka's judgment, that a parasitic etiology has been correctly assigned for these cases. These mental disorders are usually of acute type.

The parasites which have their seat low down in the bowel have a less direct relation to mental disturbance when, as in not a few cases, they provoke masturbation by the scratching of the anus they cause, or by wandering into the genital passages. The forms thus produced vary from the precipitation of hebephrenia to a stuporous insanity, or an acute hallucinatory confusional insanity of favorable prognosis.

As to frequency, Dr. Sarah B. Welt²⁰ remarks that insanity in the first ten years of life, aside from idiocy is very rare. Out of ten thousand inhabitants, Emminghaus found in Germany, between the first and fifth years, 0.18 per cent. insane; between the sixth and tenth years, 0.69 per cent.; and between the eleventh and fifteenth years, 1.46 per cent. insane. Deboutteville, in France, found among the insane admitted to the asylum in Saint-Yon from 1827 to 1834, 0.9 percent. between the fifth and ninth years; 3.5 per cent. between the tenth and fourteenth years; and 20 percent. between the fifteenth and twentieth years. Turnham found but eight children less than ten years of age among 21,333 insane; idiots, who are far more frequent in number, not being included. The most common mental derangement in childhood is idiocy, be it congenital from insufficient development of the brain, or acquired from previous cerebral disease. Next in frequency is maniacal exaltation, while depression occurs only in late childhood. Insanity in childhood in her opinion occurs more frequently than is evident from the statistics. As no psychosis in childhood shows the entire complex of symptoms as in adults, it is readily understood that the symptoms of a mentally deranged child may often be taken to be bad behavior, and only the result, mental weakness, will be recognized.

The neuroses, properly so-called, are beyond the scope of this article. All of them may be accompanied by psychical symptoms. Hysteria, convulsions, ecstasy and chorea may occur in epidemic form especially during religious revivals. The child crusades were mixtures of these epidemics with psychical ones.

Epilepsy and hysteria in childhood as in adult age present their characteristic mental phenomena. Extreme cruelty, as in the case of the boy fiend, Pomeroy, may long be the only manifestations of the epileptic neurosis. In this age it is well to remember that as Griesinger has shown mental derangement often appears as moderate irritability, persistent or habitual. The child is passionately obstinate, quarrelsome, malignant, and even immorally inclined. Often this mental degradation is dubbed simple wickedness. It may occur as a simple, logical perversion with aimless, errand tendencies, intellectual and emotional perversion with excitement. These children can not keep still a moment. They talk incessantly and incoherently, and are very inattentive. There are sometimes longer or shorter at-

¹⁷ *Journal of Nervous and Mental Disease*, 88, 1, 1880.

¹⁸ *Keating's Cyclopedia*,
¹⁹ *New York Medical Journal* March 18, 1874.

tacks of mania. In children of from 3 to 4 years attacks of crying, of wild refractoriness, of striking and morbid destructiveness occur. These may alternate with epilepsy, chorea, stupor, catatonic catatonic states (simulating katatonia). The child may remain for hours or days as if quite absorbed, with open eyes, fixed countenance and peculiar position, sometimes breaking out suddenly into loud cries. Hypochondriacal states develop in children of parents morbidly anxious about the health of their offspring.

According to Shaw¹⁵, in children the ideas are simple, few and disconnected. They are therefore incoherent because of an absence of organic associations between the residua. The morbid phenomena are not systematized as in the adult, and the result is (according to Maudsley¹⁶) delirium rather than mania. The morbid idea in the child's mind having little range of action acts downwards (Maudsley) on the sensory ganglia, causing hallucinations or giving rise to morbid impulses. These impulses constitute impulsive insanity, called by Maudsley, monomania, and by Morselli, paranoia rudimentaria impulsiva.

Under the head of monomania Maudsley places the epidemics of morbid ideas which have from time to time in the history of the world affected children. The ruling instinct in a child of 3 or 4 is self-gratification, involved in which is a tendency to destroy what it dislikes. Its insanity is manifested by perverse and unreasonable appropriations of whatever it sees, and by extreme destructiveness. It suffers from the instinctive variety of moral insanity. Maudsley describes a cataleptoid type of insanity resembling katatonia.

The instability of childhood is shown in the presence of garrulity, melancholic depression or excitement, maniacal exaltation of the pleasant deliria type and instinctive tendencies. Exaltation and delirium is usually contemporaneous with the beginning and acme of febrile attacks, while depression usually follows the disease. The temperature at which delirium begins in a child is, as Clouston has shown, a good index of its brain constitution and temperament. The temperature at which delirium sets in is lower in the sensitive. Such children, independently of temperature, are subject to gusts of unreasonable elevation during which they are quite beside themselves, rushing about wildly, shouting, fighting, not really knowing what they are about; this coming on at intervals like the attacks of disease.

Scherp¹⁷ finds that mania of sudden inception and furibund character is the most frequent acute type. Melancholia often originates in hallucinations and has a tendency to hypochondriacal phases. Katatonia may occur. Impulsive monomania, paranoia, periodical insanity, and moral insanity are more frequent than the acute psychoses.

In W. A. Hammond's¹⁸ experience the most frequent type of insanity in children is mania, but insanity in children may occur as an affection mainly of the emotions or as characterized by blind and unreasoning impulses to deceit or violence. Fixed delusions are not a prominent feature, but there are perverted feelings, indecency, destructiveness, malignancy toward relatives and hallucinations.

Kernan¹⁹ agrees substantially with Clouston and Griesinger, but has noticed that hallucinatory types are relatively frequent.

Hecker, Kerlin and Kessler find heretofore types of insanity in children marked by disagreeable variable temper, irritability, lack of self-control, morbid egotism, and often one-sided ideas of persecution at times, with impulsive and immoral tendencies.

Kirchoff finds that children whose ancestors have suffered from psychoses or neuroses, not alone become delirious from slight causes, such as digestive disturbances, slight fever, teething, etc., but are apt to be depressed for a long time after the ordinary disagreeable events of daily life. Mental work at school rapidly exhausts them. Fright and punishment excite them to a dangerous degree.

According to Moreau de Tours, circular and periodical insanity in childhood resembles in all essential particulars the same psychosis in the adult.

Pottier²⁰ insists that persecutory delusional paranoia presents special characters in childhood. They are wild, unsocial, inclined to solitude and isolation, somber and taciturn, defiant and suspicious, living apart from their comrades, regarding these last as scoundrels, and already interpreting to their disadvantage the most insignificant event. Such a delusional state may of course have the usual forensic results.

Morbid jealousy may present itself at an early age and exercise a decidedly deleterious influence on the heart of the child. Love, according to Descurret, explains the passionate attachment often displayed by little girls for dolls. In the degenerate, romantic love may occur early. Byron at the age of 8 was passionately in love with Mary Duff, a little girl of 10. The news of her marriage eight years later caused convulsive attacks. Alfieri and Dante were similarly in love at 9 years. Such early love must be regarded as morbid and an expression of degeneracy like precocity and early puberty. In the cases reported, other evidences of degeneracy existed. Like all precocity it needs restraint, not assistance. Pathological anger is exceedingly frequent in childhood. Imperative conceptions of all types occur. Hughes²¹ has observed pyrophobia in a boy of 6, who doused all fire with water. Agorophobia, mysophobia, chlorophobia, etc., also are relatively frequent.

The discussion of the "imperative acts" following imperative conceptions involves many mixed states closely bordering on delusional conditions, from childhood's instability with regard to the difference between the subjective and the objective.

With the increasing social tendency to expose children to financial and other mental stress at the critical period antecedent to puberty, suicides, insanity and criminality among children must, in the nature of things, increase. In evidence of this, Moreau de Tours gives the following table:

Years	18	19	20	21	22	23	24	25	26	27	Total
1811-1820	1	2	11	6	3	4	1	1	1	1	34
1821-1830	1	1	1	9	3	4	0	1	1	1	21
1831-1840	4	2	2	11	5	4	0	1	1	1	37
	26	37	35	36	23	11	5	4	3	3	188

In the last ten years, forty-two boys and fifteen girls attempted suicide in Russia. In the fourteen

months ending December, 1891, 62 children committed suicide in Berlin, Germany. The youngest had not reached the age of seven. The percentage there is higher for the same reason which will increase it here; the increase of school over-pressure. The exciting cause of the suicide is usually a trivial one. One boy killed himself to get rid of "so much dressing and undressing." No less than five attempts at suicide were made during 1887, by children under 14 years of age, resident in a Philadelphia district less than a mile square. In three cases the attempts were successful. In three of the five cases the moral epidemic nature of suicide was shown in the fact that one suicide was an exciting cause of two suicides and one attempt. In all five cases, the approach of puberty had produced its usual emotional disturbance. The immediate causes were, as in most child suicides, trivial. Hanging was the favorite method, although one girl (who seems to have formed the melancholiae delusion that she had hanged one playmate who committed suicide) took landanum. She recovered from the poisoning and the melancholia. St. Louis has recently had a very similar epidemic. Griesinger states that 6-10 per cent. of the suicides in England are of children under 10 years. Death does not inspire children with the same fear it does the majority of adults, and the weak ego is easily overcome by the dominant idea of suicide.

In dealing with the question of homicide it should be remembered, as Clifford Allibret²⁶ points out, that in children homicide is, as a rule, an unreflective act. The act is in all probability imitative as a rule. The child has heard of killing and of death but has no clear perception by reflection of their meaning. Homicide by negro children is growing far from rare. In two instances in 1892 two ten-year-old negro boys killed a baby brother to get rid of the trouble of minding it. Moral imbecility may crop out here and in cruelty to animals. Moreau de Tours²⁷ cites a case in which a four-year-old boy chopped at the face of a ten-months-old nursing. Esquirol has observed a prematurely nubile girl of 8 years who had a fixed tendency to kill her stepmother. Legrand du Saulle reports the case of a five-year-old boy addicted to masturbation from his third year who had long been noticed by his nurse to be wicked and vicious, who loved to torment younger children. He liked to see chickens killed; ordinarily stupid, his intelligence was shown only in mischief. Having noticed nose-bleed follow the fall of his baby brother he felt an intense desire to see blood flow. Profiting by the absence of the nurse he flung the baby down from a table. Epistaxis resulted and he rubbed his hands gleefully in blood. With complete indifference he answered in reply to all questions that the nose-bleed amused him and he would repeat the deed. This was also excellently illustrated in one of my cases:

The eight-year-old daughter of a hystero-epileptic presented many of the symptoms of degeneracy. Intensely cruel, she took delight in torturing those of a weaker nature than herself. She was constantly calling the attention of a melancholic to the screen in her window. She knew how to induce hysterical attacks of her mother and delighted in them. She delighted although afraid of her mother at that time. She delighted in the sight of blood. She was a constant liar. Imperative hallucinations had been demonstrably present for more than a year. Like so many of these degenerate cases, she had an intense appetite for meat.

The crimes of Pom-roy, the "boy fiend" of Massachusetts who killed and tortured several small children, were later explained by the appearance of epilepsy, and other cases of children homicides have had like explanations. The impulsive type can, of course, occur without epilepsy since the feeble "ego" of the child is as easily overcome by the homicidal as by the suicidal impulse.

Arson results as (Legrand du Saulle remarks) in maniacal, emotional and depressional states, in deliriums, imbeciles and idiots. It may also develop in girls ere puberty or as Marc has said, in child servants badly treated by masters and desirous of re-entering under the parental roof. Nostalgia results. Fire and flames are found to relieve this, whence arson. Rape may occur from early precocity in both sexes in the degenerate. Thefts often occurs from the same feebleness of the ego which results in homicide and suicide.

Dr. KIERNAN—There has been too great a tendency in latter days to put heterogeneous psychoses into the Procrustean bed of insanity. It not infrequently happens that acute insanity is paranoiacal even when senile. Such cases are frequently curable. It very often happens that an old gentleman is locked up and regarded as incurable when some treatment would improve his mental condition. With regard to the point raised about parietic dementia after sixty years of age, it is well known that there is an enormous number of such cases on record. There has been a tendency to call that senile or latent parietic dementia. I remember two cases in the same family which elucidates the point that parietic dementia in one generation may occur late and in the next one early. In the cases I mention the father had it at 65 years of age and the son at 25. The various types need more than an ordinary line of demarkation and for that reason I am glad to see the subject brought up.

With regard to the second paper, of course in a general way many of these mental phenomena in children pass unnoticed. There is a great tendency to ignore mental symptoms of ordinary disease and under ordinary circumstances. It shows a tendency in a right direction when we begin to study mental disorders resulting from various diseases.

Dr. FRANK T. NORBURY—I was quite pleased to hear the presentation of the subject of mental affection in children. I was associated for a time with a feeble minded institution, and having cases coming into the institution from three years up to about twenty, probably the oldest children being about twenty. I had some very interesting cases under observation. While most of them were cases of marked idiocy, yet there were many of them practically of recurrent insanity. The doctor speaks of Dr. Kerlin's observations. It was in the institution of which he was the superintendent that I served a term and where I met three cases of special interest; all these cases were females and did not come under my special charge. The cases of paranoia in childhood, that is those which I would class as paranoia, are probably not frequent, but yet there were at that institution several, one of which had very thoroughly systematized delusions of persecution, and another one had some hallucinations at intervals accompanying these delusions. I have had quite a number of children presenting epileptic insanity, and we received them in the Illinois institution. I had one child 7 years of age committed as insane to the Illinois Central Hospital for the Insane, a boy who presented the symptoms of epileptic insanity quite similar to those of an adult. We had several cases in one winter, but we have not at present any under 15 years of age.

Dr. A. : Some day I shall be able to tell you that I have a greater sympathy for the family than I have for their patients, but I want to start a case. I have done recently. I had a case of some insanity on the family, been warning the members of the family, and the family were four married daughters who all had children, the family history being bad, about the care of the children. An expert was called into the case and when the daughters questioned him, for I suppose I had aroused their fears, he said: "Oh, no, there is no danger; you need not take extra care of your children. It is only the strong-minded who get insane anyway." I have lost my hold on that family. I feel that it is a necessity in such cases for the physician who comes into a family and finds this difficulty to warn the family about the care of the children. Yet it is done almost never, where the family really should be warned about the care of their children. The children are allowed on the street late at night, allowed tea and coffee that even healthy children should not have, and yet they have never been warned.

SOME REMARKS ON INSANITY OF THE AGED.

Read in the Section of Neurology and Medical Jurisprudence at the
Forty-fourth Annual Meeting of the American Medical Association

BY FRANK PARSONS NORBURY, M.D.

JACKSONVILLE, ILL.

Lecturer on Nervous and Mental Diseases, Keokuk Medical College,
Keokuk, Iowa; late Assistant Physician Illinois Central
Hospital for the Insane, Jacksonville.

The tenure of normal mentality in old age depends on the sum total of vitality originally deposited and the maintenance of normal equipoise in the brain machinery during the years of active engagements in the affairs of life.

The blending of the normal and abnormal mental states renders the psychological study of old age difficult, because what is the normal tenure of one approaches the abnormal change in another; the result is, as Clouston has remarked, "the psychology of old age has yet to be written." To the confusion arising from the differentiation of ordinary functional derangements from organic brain diseases, is due the difficulty of diagnosis and clinical classification, which must be experienced to be appreciated.

In a clinical study of 196 cases of insanity, occurring in men over sixty years of age, coming under my care, I have been struck by the heterogeneous symptoms, yet similarity of mental affections, when modified by the influence of senility. Senility seems to be more or less a common mold in which the mental disorders of the aged are cast, for the mark of the senile change is on them all. It is because of the modifying influence of senility, causing variability in the tenure of normal mentality and confusion in abnormal manifestations of intelligence, that there is such a wide difference in the classification of the insanities of the aged. In looking over the reports from some thirty prominent State institutions for the insane, I find it is, more or less, the rule to classify distinctive insanities of the aged as senile dementia. While it is true senile dementia is the only characteristic alienation of the mind when in its uncomplicated form, conforms more to a distinctive type than any other one form of insanity of any age, yet we must not forget that we have other types in the aged as much entitled to consideration, both pathologically and symptomatically, as senile dementia. Indeed, all things considered, it seems

dementia or cerebral syphilis, but are distinguished from them by other associated symptoms, especially of cardiac and renal origin. Vertigo is quite noticeable as before mentioned and is probably due as Hirt says, "to the atheromatous condition of the arterial walls, and the consequent irregularities of the blood supply to the brain substance."

The melancholia of chronic atrophy is, we believe, dependent alone on those circulatory changes. All have noticed in attacks of acute melancholia of the aged, where cardiac disease was conspicuous, the dependence of mentality upon the stability and regularity of the heart's action. In a study of probably thirty such cases, during the past four years, I have satisfied myself that more than renal disease is necessary for the melancholia of cerebral atrophy, and that the circulatory changes are, primarily, the cause of such mental depression. Again, the manic outbreaks of chronic cerebral atrophy with their explosiveness, incoherence and destructiveness may be of cardiac origin. I have noticed, especially in cases complicated with angina pectoris, that the mania was very severe and distressing. The fear of impending death, to be noticed in individuals not insane is, in the insane, transposed into hallucinations and delusions, destined to cause great mental disturbance.

In the ordinary senile dementia we meet with destructiveness, filthiness and incoherence; the physical and mental helplessness being but the result of the progress of disease.

The decline is gradual; the slowness of the atrophic process producing mental symptoms is, at first, regarded as but the natural result of old age; the amnesia, the sudden changes in moods and emotions, and the appearance of delusions being the evolution of distinct senile dementia.

The minor details are familiar to you all, and cause you more or less anxiety in their treatment, especially at their homes. It is the persistent wakefulness at night of such cases and their tendency to wander away from home, that ultimately leads their friends to have them committed to the hospital. Here the career of helplessness goes on until death sooner or later closes the scene. In brief, I have presented the characteristics of these two *distinct* mental diseases, having *distinct* symptoms worthy of more study from alienists, especially in their pathological differentiation, which is too much ignored.

Another organic disease of the brain, however not frequent, but still it does occur after sixty years of age, is parietic dementia. Steadman says that it rarely occurs after fifty, but I have, in the 196 cases of insanity occurring in men over sixty, found seven marked cases. Mickle has observed that "owing to the brain strain and exhaustion of the over pressure and blood deprivation in modern life, general paralysis tends to occur at an earlier age than formerly." I may therefore look upon this series of cases as of rare occurrence. I rather believe in the agricultural communities, from which most of my patients came, the longevity of such people may be considered as a factor in the cases I have observed. Nothing out of the ordinary was noticed in the cases, except in the postmortem examination of one, the very thin skull was interesting, for it is usual, as Wood says, to find hyperostosis and exostosis on the skull. This skull was so thin that objects could readily be distinguished through it.

Syphilitic disease of the brain was observed in five cases; one made a good recovery, three died and one is still under observation. The diagnosis of intracranial syphilis in the aged is difficult, but the symptoms, as outlined by Gray, have materially assisted me in making what I believe to be a correct diagnosis in the five cases above mentioned, the mental symptoms of course confirming my belief. The suspicions and hallucinations being especially marked.

General paralysis may occur beyond sixty years of age.

Syphilitic insanity should not be confused with senile dementia, and the treatment of syphilitic insanity must be vigorously pushed in the aged to avoid chronicity.

In conclusion, gentlemen, I would say that the differentiation of the insanities of the aged are too carelessly observed in our State hospitals for the insane; that the attention to their pathology is neglected and the observation of special symptoms ignored. The recoverable attacks of mania and melancholia being too often classed as chronic insanity, and the recurrent attacks of mania and melancholia in chronic cerebral atrophy classed as acute insanity.

We need more attention to the study of the science mind, and less politics in our institutions to bring them up to the standard of foreign hospitals.

SOME MEDICO-LEGAL EXPERIENCES IN RAILWAY CASES.

Read before the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association.

BY THOMAS G. MORTON, M.D.

PHILADELPHIA.

Railroad injuries, from a surgical point of view, possess many features of interest; not the least of which is the medico-legal question concerning the gravity or reality of alleged injuries for which pecuniary compensation is demanded.

At a time when he least expects it, in these days of rapid transit and frequent travel, any individual may be obliged to witness, participate in or be the victim of a railroad accident attended by loss of life or by various degrees of traumatism—maiming, contusion or concussion, and every surgeon is liable to be called upon to render assistance to those injured or claiming to have been injured by such an occurrence. Experience, however, has taught us to exercise special caution and to express a very guarded opinion as to the prognosis or gravity of a traumatism occurring under such circumstances. Suits for damages are so common that the surgeon or physician almost instinctively recognizes these patients and governs himself in accordance with this fact, knowing that the attempt may be made to use him as a means of extorting large sums of money; indeed, he may even unconsciously become an innocent party to a conspiracy to defraud the railroad company defendant.

Under such circumstances it would seem proper that we should consider this question, which, although largely medico-legal, is still more one of diagnosis

calling for a high degree of skill to separate the time from the fraudulent claimants. I compared a brief resume of several recent cases to illustrate the tendency above referred to and tried first to present briefly a few of the more typical characters which distinguish this class of non-ordinary surgical injuries. The most evident one in these patients is a psychological one arising from the prospect of receiving damages in a malcorroboration by simple and easy means.

The fact that courts and juries are popularly believed to sympathize with the plaintiff in these cases and the corporation defendant is popularly presumed to be guilty until proved to be innocent, has doubtless effect in stimulating such litigation.

The number of persons in the United States actually claiming to have been more or less seriously injured upon railways is very great; many of these cases are beyond all doubt fictitious and fraudulent. Upon good authority it has been stated that E. R. R. railways have paid, within a period of five years, upwards of eleven millions of dollars damages for spinal injuries alone. I believe that I am correct in stating that more or less exaggeration is present in nearly every case of railway injury. In the attempt to impress the court and excite the sympathy of the jury, very frequently the person claiming to be injured will go close to the border of imposition, even though he justly claims compensation for actual injuries. On the other hand, the willingness of railroad companies to settle such cases outside of court tends to make prompt compensation for actual injury, serious or loss of time, is so well known that designing persons attempt to take advantage of the weakness of fraud and even actual conspiracy to defraud is not infrequent.

Prompt settlement for injuries can generally be made on more favorable and satisfactory terms immediately after the injury has been sustained, and in this way a mole-hill can often be prevented from growing into a mountain because so long as the claim is unsettled, ill-health continues. In fact, the possibility of permanent disability is always made a prominent feature, and every occurrence in the subsequent medical history of the claimant is apt to be traced back to the accident as an additional cause.

Medical expert testimony is commonly sought by the plaintiff and the court and jury share the confusion of being embarrassed in arriving at a just verdict. Among the disturbing elements may be mentioned the possibility of the plaintiff's counsel in suggesting the dreadful possibilities of the future and in so doing painting them in lurid colors. Thus the medical witness is often questioned concerning the possibility of cancer resulting from a contusion or of displacement of the uterus, the development of tumors or of pelvic inflammation; all of these being the effect, perhaps, of a trivial injury whose external effects are transitory and insignificant.

Lateral spinal curvature has even been reported to be caused in this way, which has been substantiated by findings to be due to congenital asymmetry of the lower limbs, as will be observed in two of the three above cases appended to this paper. Indeed, it would seem, in the opinions of some, that any of the flesh which is heir to may arise from railway injuries. The readily recognized maladies and deformities resulting from railway injuries are settled with less difficulty.

[illegible]

11. Most stressors are non-lethal, and the effects of stressors are often cumulative. The effects of stressors are often cumulative, and the effects of stressors are often cumulative.

[illegible]

Other structures within the nucleus are found in much more restricted regions. The nucleolus, for example, is found in one particular region of the nucleus, and is especially prominent in certain tissues. It is composed of exposed ribosomes, strands of ribonucleic acid (RNA) and proteins which are strongly attracted to each other.

From these numerous firms, called for under the act, the government has received only a small number of returns. It is unable to determine the corporate income tax status of many of the "expected" returns, and so has not announced until the present date the other half of the revenue which it is expected will be received. It is well as the Government is informed that the "small" expectations of Federal income tax revenue are based upon a study of the returns examined in the "terrible" effects which are said to follow a change in the spine. In the records of such examinations are the so few, it is said, and the number of returns.

those who have claimed to have the injury, that the skeptics are somewhat justified in attributing the few cases which have shown great pathological changes in the cord and its membranes to the coincidence of disease, as myelitis or syphilis, or to much graver injuries than concussion.

I may say, after looking back upon a very large number of cases of railway injuries, real, exaggerated or feigned, upon which I have been called to give an opinion that I am not conscious that any injustice has been done in a single case. On the contrary, where the claimant was judged to be a malingerer, or that fraud was attempted, the subsequent history of the case has been such as to strengthen and confirm the opinion, and on several occasions, the attempt at fraud has been confessed or the conspiracy revealed.

At the present day the simulation of disease can rarely be successfully carried on, provided the medical attendant makes use of modern means of diagnosis and is familiar with the symptomatology of the feigned disease. Instruments of precision enable us to attain accuracy of observation, which very promptly enables us to recognize such cases, so that fraud is detected with more certainty and its character made manifest to court and jury. Impostors, therefore, are less likely to enter suit when they know that it will be contested by the railroad company and the actual state of the case brought out in testimony.

In many cases, settlements are declined and consequently a defense must be made by the railway corporations, or the treasuries might at once be opened unrestrictedly to all applicants; in view of the possibility of a settlement being refused, it is important for the railways to secure, not only an examination of the injured person soon after the accident, but also an examination before the trial; such evidence may reduce a verdict, or even obtain one for the defendant. Juries, however, usually sympathize with the plaintiff and can hardly be said to carefully weigh the evidence when their sympathies are aroused by the plea of mental and physical suffering or by the sight of bodily injury or deformity which is always made as prominent as possible. A common method, it is said, of arriving at the proper amount of damages, is for each jurymen to name his idea of the proper sum to be awarded, and these sums to be added together and divided by twelve to get the result. In some instances it would seem that the last step (of dividing by twelve) had been omitted.

Occasionally the gallantry of a jury is not appealed to in vain; in a recent case, a husband was killed upon a track where it was shown he had no right to be. Although it was agreed that the widow had no claim, a sentimental appeal was made simply for the widow to the jury, who gave her a verdict of \$1,200. The foreman of the jury was subsequently asked how it was that such a small sum was given, and that the widow had any claim at all, the verdict was increased at least \$50,000. He replied that it was because he felt that the widow could get along at \$1,200 a year, and then, as she was so young, it was probable that she would be married some one to look after her.

Such a verdict is a commentary upon human nature, and extends an additional cord to the prompt settlement—it is commonly

noticed that no matter how long the plaintiff has been a helpless invalid while the claim was pending, as soon as the settlement is made and the money paid over, he improves in health to a marked and sometimes miraculous degree.

Out of the many cases I have selected the following, which are sufficient to illustrate the points which I wish especially to submit for discussion and which may be taken as representative of the entire class.

In the suit brought by the driver of the coach in which said Smith was injured, he got a verdict of \$6,000. We got a new trial and paid \$1,000 in settlement. He claimed injury to spine. I afterwards saw him running across Independence Square as swiftly as a deer and as straight as an Indian.

Several of the cases (4, 5 and 7) reported occurred in the service of the Pennsylvania Railroad Company, and in these the examinations were made conjointly and the opinions formulated with my associate, Prof. William S. Forbes of Philadelphia:

Case 1.—Conspiracy to recover damages from the Philadelphia Traction Railway Company for injuries self-inflicted.

Henry S., a young man, was standing on the platform of a Philadelphia traction car and was thrown off while rounding a curve at 6:30 in the afternoon of May 16, 1890. The lad was picked up, found to be considerably injured, and was taken to the Jefferson College Hospital, where it was found that he had sustained a fracture of the left humerus.

The reports of the conductor and passengers showed that the lad was told to take a proper position, and to be on his guard at the rounding of the curve; and that there was nothing to cause him to be thrown off, as the car was about stopping. This led to suspicion and an investigation, and the following was discovered:

Harris P., and Passa P., his son, aged 16 years, and Henry S., his son-in-law, met and adopted a plan to swindle the railway corporation and concluded that one must be injured by an accident due to jerking of the car. After some argument the lot fell to the son-in-law, Henry S., to fall off the car on the date mentioned. Henry S. got on the car, stood on the back platform, and as it rounded the curve (the place agreed upon) he placed his back towards the sidewalk and deliberately stepping backwards, rolled off. It was also discovered that the plaintiff had secured witnesses to observe the accident; the jealousy and cupidity of these persons divulged these facts on account of the large sum of money the plaintiff expected to receive.

It was also found that Passa P., the son of the originator of the conspiracy, was present at the scene of the accident, awaiting its occurrence, and reached the hospital before the injured man arrived. This led to the arrest, trial, conviction and imprisonment of the three conspirators.

It was subsequently learned that Harris P., the father, had been convicted of similar crimes in Russia, and that the three had swindled other corporations in Philadelphia.

Case 2.—Conspiracy to defraud the Traction Railway Company.

The trial of the action in this case was brought by Nicola Flore against the Philadelphia Traction Railway Company to recover damages for personal injuries received, which injuries, it was alleged, were of a permanent character; a lateral curvature of the spine having resulted, and necessitated the wearing of a plaster jacket by Flore.

The defense was that the claim was fraudulent and a conspiracy to defraud the company.

Dr. Wm. Pepper, Dr. Thomas G. Morton and Dr. Horatio C. Wood were called by the defense, and taking Flore from the court-room into an ante room, they made a physical examination of his condition, first cutting from him the plaster jacket which he wore. At the end of the examination they came back into the court-room and testified that they found a congenital shortening of one leg, a scar from a wound on the back near the left shoulder, and that with these exceptions there was nothing the matter with the man at all.

They further testified that while making the examination they subjected him to certain tests, as to the location of pain, etc., and found from his answers that he was feigning. As to the plaster cast jacket, they said that, while in some

instances, such an appliance might be of use, there was no necessity for the use of it in this case not the slightest particle of necessity for the use of it.

On behalf of Flore, a counter-conspiracy on the part of the Traction Company was alleged. The counsel for the plaintiff in arguing the case for Flore to the jury, asked them to give his client special damages; while the counsel for the defendant, on behalf of the Traction Company, suggested that the jury should give Flore nominal damages of damages originally laid, or believing him to be a fraud, should give him nothing.

The court, after defining the law, said: "It is charged here that this case has been manufactured; that the injury has been greatly exaggerated; that the plaintiff, with the assistance of others, has attempted to deceive you and to pretend that that which was really but a trifling hurt, was in reality a permanent injury, affecting him for life. If you believe that, of course your verdict ought to be for the defendant, because a man who will grossly and deliberately falsify his oath and swear falsely to you intentionally, ought to be dishonored entirely, and he is getting off very well if he goes out of court with the verdict against him. It is a case for your common sense; apply it to it."

The jury, after a deliberation of about ten minutes, rendered a verdict for the Traction Company.

Case 4.—Trifling or simulated injury greatly exaggerated. Erichsen's railway spine claimed to have resulted.

Arbitration unanimously awarded a verdict for the defendant; appeal and trial before jury, who with exactly the same evidence gave a verdict for the plaintiff; an appeal to the Supreme Court and a new trial; amicable settlement effected.

Mr. A., a resident of Pennsylvania, stated that about 10 a.m. in May, 1891, while seated in a car looking out of a window, when his body was partly turned, a sudden coupling of the cars jerked him backwards, twisting or spraining his spine. He immediately rose in his place and exclaimed, "My God, my back!" At this time he said that he had a pain as though something pierced him, in the small of the back, that his speech stopped to a certain extent, and became very jerky. He continued his journey when the cars started in a couple of minutes or less, and on arriving at his home at noon he changed his clothing, ate his dinner, and in the afternoon went to work as usual. While at work playing, his back hurt him so much that he had to quit work several times. He worked several days before going to a physician, and on doing so received a strengthening plaster which he applied to his back, and continued to work, off and on, until February or March of the next year. In October previous, he had applied at a general hospital for rheumatic pains.

Finally a claim against the railroad was brought for a large amount of money for permanent injuries. Mr. A. testified at the trial that he had suffered pain from the moment of the accident; that he had not the proper strength in his arms; that sleep was interrupted; there were tender spots on his back, etc. The medical testimony offered by Mr. A. showed that his walk was impaired; he had terrible pains in his head; he was nervous and irritable; he had a swelling over the small of the back on one side; the spine was rigid as though it were a piece of solid steel; there were terribly contracted muscles; a peculiarity of speech; a jerking of his voice when attempting to speak; that when he attempts to lift his arms above a right angle with his body, he can not speak at all; that for many weeks he did not recognize any one; that he had been insane; unable to lie in bed, only on the floor; had lost control of bowels and bladder, etc. In answer to a question, his medical attendant stated that he was suffering not only from hysteria, but from Erichsen's disease, or railway spine, and that he had been seriously and permanently injured by the sudden twisting of his back.

An examination of the plaintiff, with Dr. Charles K. Mills, discovered that, although a neurotic, yet he was unquestionably a malingerer of the most pronounced type. He had previously been treated for lumbago, and he had lost much time from his trade as jobbing carpenter on this account. There was no evidence of spinal lesion, or that so-called commotion of the spine had occurred. There were some symptoms which might charitably be ascribed to hysteria; but his jerky speech was purely simulation, and he attempted to deceive while testing his hearing. He was of neurotic ancestry, and some of his relatives had been insane. His general standing in his community was not high. The settlement of the case was left by agreement to arbitrators who, after a very protracted inquiry, taking

every particle of evidence obtainable, gave a verdict for the railroad company. An appeal was taken from the result and the case was tried in court, and the result was exactly the same evidence, and a verdict for the railroad company appeared and was granted a new trial, in which time came, however, a settlement was made for full for \$1500.

Case 5.—Injury to a passenger by a car wheel striking him on the head, resulting in a permanent injury.

W. H. was a passenger in a car when a wheel struck his track and partly turned over by the spreading of a rail. Immediately after the accident he was able to get up and was at home in time to his bed, and on the second day afterwards, he drove in a buggy some ten miles to see a physician. He was afterwards brought for his injuries, and five months after the accident, an examination being allowed, the following report was made:

W. H. stated that he had, at the time of the accident, received a wound of the thumb and an incised wound of the ear; he also stated that a part of the seat of the car was pressed in upon his right groin. His physician, who was present at our examination, stated that there had been a partial fracture of one rib; also that the patient had suffered from hemorrhages from the lungs, with some purulent discharge at such times; that there was incontinence of urine, which necessitated the frequent use of the catheter; that the testicles had been injured; that there was abdominal dropsy, as well as general dropsy of the extremities; and that he was suffering from injuries which not only had seriously compromised life, but that he was also permanently injured.

Upon examination, H. was found to be 46 years of age, a very large man, well developed, weighed perhaps 225 pounds; he was sitting down stairs when we arrived, readily got up out of his chair, and walked without assistance or effort to the second story for our examination.

The incised wound of the ear and the thumb had healed with a slight scar; the joint of the thumb had evidently been opened, for complete ankylosis had resulted. There was no other evidence of injury about him, and on our asking his physician to point out the site of the partial fracture of the rib he was unable to locate the injury, and when he indicated as about the place, the latter was not where any rib existed; in other words, it was to the sternum our attention was called.

There was no effusion into the abdominal cavity, nor was there any swelling or dropsical condition of the limbs. There was no evidence of any lung or heart trouble. In regard to the incontinence of urine, the only appearance which would sustain this was the presence of a wet spot upon the patient's shirt, but the usual indications found in incontinence were absent; in other words, there was no urinous odor about the parts, no soaked appearance of the penis and scrotum, no irritation about these parts incident to the constant presence of urine—the mouth of the urethra was normally dry. With forced inspiration and expiration the testicles were elevated and depressed normally; they were of normal size and properly located, nor was there any evidence of their ever having been injured; no adhesions such as would be present had there been any local inflammation as a result of injury; the scrotum was normal. The patient was apparently very sensitive to the least examination of the testicles, and complained of intense pain with the slightest examination by finger pressure. When the chest and abdomen were examined by percussion which presented no variations from the normal state, the results showed no evidence of variation from health.

Conclusions: The statement that the patient has from time to time more or less severe hemorrhages from the lungs and stomach is not borne out by examination, for it would be impossible for him to have such a condition without more or less disease, which could be ascertained. If he has any such loss of blood, it certainly is from the nasal region and quite innocent in character. The appearance of the discharge he is said to have, and in favor this view, because it is colored, and the associated discharge said to occur is probably nasal and from the nose. In other words, there is no evidence of any pulmonary or cardiac disease, which must be present to variant any other view.

There may have been some bruising of the groin, but if such an injury did take place, there is no evidence of it at this time. The internal abdominal organs are normal, and the fact that the patient and his physician have been in error as regards the dropsy of the abdominal cavity and

the limbs shows conclusively that a great mistake in diagnosis has been made.

There are no symptoms present which indicate any permanent injury of any organ or part—in time he will unquestionably be restored to his usual health, except the ankylosis of the thumb, and some trivial scars; and further the examination warrants the belief that the case is an unmitigated fraud.

The jury rendered a verdict for \$16,000, and the court promptly decided to grant a new trial, or a reduction of the verdict to \$10,000; the latter was accepted, and paid by the company.

A year or so subsequent to the settlement, the wife of the plaintiff voluntarily came to her husband's counsel, who communicated her statement to the counsel for the Pennsylvania railroad company, that her husband received only trifling injuries in the accident; that he worked for a week afterwards at his usual vocation—a butcher, peddling through the streets—and that he then conceived the idea of making a claim against the company; that he had none of the troubles which he swore to having on the trial, and that he did not dare to call her as a witness because she would have sworn that his testimony was untrue. She further stated that he was not impotent, having had sexual relations with her four times during the week the trial was going on, and was also discovered with the housemaid; that he had entire control of bladder and rectum; that the blood he said was expectorated, was brought to him from the butcher; that soon after receiving the payment from the company, he went to Scotland and had not been seen since.

Case 5.—*Lateral spinal curvature, claimed to have resulted from injury, but was demonstrated to be due to asymmetry of the lower limbs.*

Mrs. L., aged 36, claimed that while sitting reading in a car she received a sudden jar induced by the coupling of a car to the rear of the train, by which she was thrown forward, striking her forehead against the frame of the window. No other passenger was injured. When she was examined by a surgeon soon after, no evidence of injury was seen except a slight wound on the forehead. After reaching her home, some hundred miles further on, she was attended by her family physician, who stated that he found her suffering with sick stomach and severe pain extending down the spine to the sacrum. These symptoms continued, the spinal pain subsequently became paroxysmal, and later on a lateral curvature was discovered; the patient, however, was up and about, and gained in flesh. She claimed that either walking or working aggravated the spinal pain; but she considered herself, on account of the spinal curvature, a confirmed invalid.

An examination was made in 1889 for the railroad company by the late Prof. Henry H. Smith, who reported that: "The patient was found in bed, where she says she has remained since the accident; objective symptoms—a slight scar is apparent on the forehead; limbs are full and round, and her weight probably 170 pounds; pulse variable, showing nervous excitement; skin has a healthy color; temperature and reflexes normal; no nerve lesion. Lateral curvature of long standing, possibly has been unknown to patient, physician or friends, but has no connection with the accident;" and the opinion was given that the case was one of hysteria with some neurasthenia.

Subsequently the claim for damages of \$20,000 was supported by affidavits from various parties, among whom were female friends who testified that they had seen her dressed and undressed prior to the accident and that they had never noticed any spinal curvature and that after the accident she walked one-sided, and badly. One affidavit from her pastor stated that she was "a woman of fine character and a member of his church in good standing, and the mother of five small children." A medical man testified in regard to the plaintiff "that he had never heard or seen any spinal trouble, any curvature of the spine; her walk and carriage was always straight, erect, and without trouble, nor did she have any curvature of the spine until the railroad accident."

Some months after this, Dr. Smith sent in another report with his reasons in opposition to the claim that the lateral spinal curvature was the result of the accident, which condition was the principal injury for which damages were claimed. This report acknowledged that a lateral curvature existed but that it certainly developed early in life; that there was no instance on record of such a curvature having developed in a few weeks by an mechanical violence, whether applied through collision of cars or other force; and the creation of lateral curvature by a sudden force applied to a

fully ossified vertebral column is a physical impossibility; numerous surgical authorities were quoted in support of this view. But the presence of the curvature was not satisfactorily accounted for, and suit was pressed.

Dr. Smith died in March, 1890. As the trial was imminent, another examination was requested and allowed. The patient was found to be in a fair condition of health; but the main source of complaint was the curvature of the spine, which it was alleged caused pressure upon the spinal nerves and a general weakness of the extremities, and generally of all the functions.

Mrs. L. was after much persuasion induced to permit a thorough examination of her spine; her back from her head to her heels was exposed. As she stood with her back towards the window, a lateral curvature was at once observed; but at the same time the line of the nates was found oblique, and the gluteo-femoral fold of right side was much lower than on the left side, showing at once that asymmetry of the lower extremities existed, which fully accounted for the curve. The right lower extremity was raised by placing books under the heel so as to equalize the limbs and the right was found to be one and one-quarter inches shorter than the left. With this correction of the asymmetry, the curvature vanished, and not a trace of the deformity could be found.

The plaintiff's medical attendants were then convinced that the curvature was a condition of early life, and had no relation to the accident; yet nervous shock, lost time and wound of forehead were deemed sufficient to claim damages and suit for \$15,000 was pressed.

Just before the trial, a settlement for \$2,500 was effected. The plaintiff, who came walking into the room on crutches and markedly lame to receive a check and sign a release, immediately after this, got up, walked out without the crutches and without any lameness; shortly after this she was married and up to last accounts was in good health.

Case 6.—*Action against the Philadelphia Traction Railway Company for \$100,000 damages for personal injuries.*

On August 26, 1889, at about eight o'clock in the evening, Mrs. M., a married woman, was a passenger as far as the depot in Philadelphia. After safely alighting from the car, she fell on the wooden floor, some five feet away; the conductor assisted her to rise, but she claimed she was unable to walk. A grocery-man near at hand had her taken home in his wagon.

The woman was attended by a physician, who sent word to the company that she had broken several ribs, seriously injured her arms and legs, and as a result of the fall had aborted, and that the fetus was preserved in alcohol.

The medical examiner sent by the company to make a report stated that he saw injuries upon the arms and legs, that she was plastered and bandaged in the usual manner for fractured ribs, and also stated that as the doctor was a reputable physician, he accepted his statement that the ribs were broken.

Subsequently the husband of the woman, and a friend, went to the office of the company and endeavored to secure a settlement for the injuries sustained by Mrs. M., and for expenses incurred.

The company declined to consider any proposition, and suit was brought against them. The severe injuries which it was claimed the woman had received attracted the attention of the legal counsel of the railroad, who, suspecting fraud, directed an investigation, which developed the following remarkable state of affairs:

The woman, Mrs. M., was intimate with the physician; that she had not sustained any injuries whatever, and was not pregnant at the time of her fall in the depot; that the alleged injuries on her arms and legs were specific ulcers; she had been under treatment for constitutional disease and for ulceration at one of the Philadelphia dispensaries some time prior to the accident. That the fetus was obtained by the doctor from a girl of loose morals who lived in the house adjoining the plaintiff; that the doctor had produced an abortion on her when she was about four months pregnant; that another physician stated that he was called upon to stop the girl from bleeding to death after the criminal operation; that this girl was intended to be a witness in the suit for damages to prove the accident, and to state that she was a passenger on the car at the time. That the husband and his friend tried to make arrangements to purchase other witnesses to testify to seeing the accident; that the two women, Mrs. M. and the girl, picked up two men on the street, with whom they had oysters and liquor, and these men were asked to become witnesses, and were promised money for the same.

It was also discovered that Mrs. M. was on the floor playing with puppy dogs immediately after the accident, showing that serious injury of the limbs and broken ribs were most improbable.

Upon this report, the parties were all arrested and tried before Judge D. Newlin Fell in the Court of Quarter Sessions, and after two full days' trial the defendants were all convicted, and were sentenced to fifteen months' imprisonment.

Case 7.—Injury due to negligence of the claimant, followed by hysteria and simulated loss of power. After accepting compensation, confessed to having a carefully taken mummy.

Miss B. stepped from the platform of a car while the latter was in motion, and in getting off faced the rear of the train, and had no recollection of stepping off, but found herself sitting on the ground bewildered. The conductor came to her and said, "Are you hurt? Can you walk? You should not have stepped off backward." Miss B., however, walked to the office of a medical man in the neighborhood, where she remained an hour and a half, was then taken to her home, and was confined to her room for some six weeks. She became insomniac and lost considerable weight. Some weeks after the accident she had a hemorrhage, apparently from the lungs; eight weeks after the injury was walking about, went on a short journey, and after this went about as usual. Damages to a large amount were claimed.

On examination, Miss B., who was thirty-eight (38) years of age, not usually emotional, but nervous and spare frame, complained that she was unable even to do any light work, and that her health had been broken up. Careful inquiry failed to detect any malady or any result of the accident; but she continually referred to compensation, and the effort was obviously made to make out the case as serious as possible.

Miss B. may have been somewhat contused and shocked, and subsequently became unmoved, hysterical and prostrated. That great exaggeration of her symptoms existed, was demonstrated when she was asked to lift one foot and then the other upon a chair; this she appeared unable to do, indeed affected not to have the power to accomplish the act. Since it had been shown previously that there was no loss of muscular power, the effort to deceive was very apparent.

There was no evidence of permanent injury; her nervousness was aggravated by too much sympathy by her friends of the church, who constantly condoled with her.

Soon after this the case was settled for one thousand dollars (\$1,000).

Some months later a lady called upon me, and seemed surprised that I could not recognize her; she then said, "Do you not remember Miss B.?" and then remarked, "I have felt as if I must see you and say that I ought never to have taken one penny from the railroad company; it was not right." And as suddenly she left.

These cases are not detailed with any idea that the presentation of the facts will make any difference in future trials of railway cases, or that verdicts will in any wise be different; yet it is well, perhaps, to place the histories of such cases before one another, so that we may be on guard in examinations, especially of persons who claim to have been damaged in railway accidents, whom we, from our observation, are led to believe are attempting deception.

AURAL VERTIGO (MENIERE'S DISEASE.)

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY L. HARRISON METTLER, A.M., M.D.

CHICAGO, ILL.

The classical experiments of Flourens, in which destruction of the semicircular canals resulted in unstable equilibrium, were so brilliant and apparently so conclusive that it seemed very proper to attribute the vertigo in so-called Meniere's disease to the hemorrhagic obstruction and consequent interference with the normal function of these same organs. Medical literature abounds with cases where-

in a sudden attack of vertigo associated with loss of hearing was diagnosed as hemorrhage into the labyrinth, without further investigation into the correctness of the inference. I have never felt convinced that such an explanation was the true one for the majority of these cases. In the first place, vertigo is a mental phenomenon of far too complicated a character to presuppose so simple an origin. In the second place, it is not positively proved that the semicircular canals preside over the maintenance of general equilibrium, for experiments have been made which indicate that they subserve in some way the purpose of hearing rather than that suggested by Flourens. In the third place, neither physiological experiment nor pathological observation are sufficiently abundant to show that the canals alone are responsible for the vertigo. Other intracranial structures have, in the majority of cases, been injured along with the canals. And finally, the absence of any positive postmortem examination showing involvement of the canals only, forbids all dogmatic assertions in regard to them being the source of the vertigo in Meniere's disease.

I will briefly consider each of these arguments and analyze a few reported cases; but before doing so I will refer to two cases that have fallen under my own observation, both of which presented the typical picture of Meniere's disease, but in which the cause of the vertigo could be easily explained otherwise than as a hemorrhage into the semicircular canals. The details of my first case will be found in the *Journal of Nervous and Mental Diseases* for January, 1891, page 19.

E. M., a German woman, 45 years of age, having a good family history, had been subject to attacks of malaria, rheumatism, asthma and dyspepsia. The pulse was rapid, irregular and tumultuous, while the sounds of the heart indicated marked insufficiency of the mitral valve, the result of an old endocarditis. Being a hearty eater, the patient retired one evening in March, 1890, after indulging in a full meal, and was suddenly awakened about two hours later with a horrible nausea and distress in the stomach. There was intolerable vertigo, violent vomiting and severe frontal headache. The vomiting continued in the morning and the dizziness became so great that standing upon the feet was absolutely impossible. The vertigo was both subjective and objective, for she beheld objects swimming about the room while at the same time she felt herself whirling about like a top. It was in the morning that she first noticed the loss of hearing in the left ear. The deafness was complete, but there was marked tinnitus, which the patient described as a "pounding on metal," alternating with a peculiar noise like "a group of birds in the grass." I could discover nothing abnormal with the ears externally. After treatment some time with the iodid of potash, the patient improved, and consented to have her ears examined by Dr. Chas. S. Turnbull. The Doctor wrote me his opinion, which will be found with the more detailed report of the case in the journal cited. The general condition of my patient, the suddenness of the attack, the unilateral character of the affection, the limited nature of the symptoms, the gradual and permanent amelioration of the vertigo, the total loss of hearing and the absence of more positive bulbar and aural signs inclined me to regard the lesion as that of an embolus in the auditory artery.

My other case I saw about a year ago. The woman was about forty years of age, with a good family history, and with the full phlegmatic type of constitution. There was no apparent cause for the trouble, as there were no symptoms of any special disease as in the former case. She was married, but childless. She retired one night seemingly perfectly well, and awoke suddenly after a few hours with a roaring sound in the head, accompanied by intense nausea and dizziness. In the morning she found herself totally deaf in both ears. An examination of the ears revealed nothing abnormal externally. Various lines of treatment proved inefficacious, and though the vertigo soon vanished and the patient regained the best of health, there was still no indication of the slightest return of the hearing. In both of these cases Charcot's treatment with large doses of quinin proved entirely futile.

The mental phenomenon known as vertigo, reveals upon close study, a far more complicated nature than a mere disarrangement of the function of any one organ, such as the semicircular canals. The study of vertigo alone is one of the most intricate in medicine, and though we are quite familiar with its subjective and objective manifestations its immediate cause remains yet a profound mystery. The maintenance of equilibrium can not be satisfactorily assigned to any single center, though its disturbance may easily depend upon a number of distant reflex disturbances. There is a multiplicity of impressions constantly pouring in upon the brain through the various avenues of sensation which must necessarily keep the mind in a state of extreme tension, so that the slightest exaggeration one way or the other will result in mental confusion and more or less vertigo. We learn instinctively how to control and marshal these ever passing sensations before the mind, but if for a time they become too frequent, rapid or sudden, the controlling force of the intellect is weakened and we are confused and overcome by them. Everybody knows how quickly vertigo is established by rapidly revolving mirrors, peculiar whirling sounds, electrical sensations upon the skin and such distant irritative conditions as dyspepsia and constipation. Physiological psychologists are agreed now that our knowledge of the relationship of things, as well as of space and its dimensions, is the result of experience gained from the use of our muscles. The infant learns these dimensions by the frequent application of its hands to the objects which it sees; and the sight, which is the only other sense that reveals to us an extended object, and that never shows us more than two dimensions at one and the same time, does so entirely through the "muscular sense" exercised in the use of the muscles of the eyeball. Now when we study the nature of equilibrium we discover that it is dependent upon a normal consciousness of the proper relationship of things outside of the centers of consciousness. It is not purely psychic as some have imagined. There is the sensation of a motor process in it. Dr. Hughlings Jackson has long insisted upon the importance of this fact, while Dr. Reynolds wrote as long ago as 1854 that "the feeling of equilibrium results from the harmony of our different sensations among themselves and with the motor impulse which is their combined effect. When any one group of the sensorial impressions is distorted or removed, the balance is disturbed and as these impressions are themselves the stimuli of

muscular action, attempts are made for its restoration . . . producing vertiginous or allied movements." The principal factors in the preservation of equilibrium are therefore consciousness and normal sense impressions. A vertiginous impression reflected through consciousness may end in a complete or incomplete motor act. In the latter case there is merely a residual disturbance of past impressions without a fulfillment of the present impulse in complete motion, while in the former the patient is uncontrollably moved in one direction or another.

If the views of Spitzka and Starr in regard to the sensory paths in the medulla be correct, they bear strongly in favor of this sensory motor theory of vertigo. Thus Spitzka concludes that impressions from the cochlea reach the cortical centers in the superior temporal gyrus by way of the posterior division of the eighth pair of nerves, the trapezium of the same size, part of the lemniscus, posterior pair of the corpora quadrigemina, external geniculate body and the corona. According to some late observations of Starr which prove the correctness of the views of Flechsig and Von Monakow, the lemniscus tract is associated with the so-called "muscular sense" and is chiefly distributed to the inferior quadrigeminal body. Some physiologists think that it is even continued up as far as the corona. It is believed that this tract is associated with the sense of sight, as well as with the coördination of movements. Flourens found that injuries to the corpora quadrigemina of one side caused "forced movements," and that their complete removal resulted in incoördination of movement, yet we have no knowledge of any connection between these bodies and the cerebellum, though it is barely possible such a connection does exist. At all events the point which I desire to insist upon is the close relationship of all these tracts for sight, hearing and the "muscular sense" in the corpora quadrigemina and their more distinct termination in the cerebral cortex than in the cerebellum. If vertigo were a kind of encephalic ataxia, and due simply to disturbed coördination, it might readily be attributed to the cerebellum and then the *probable* connection of this part of the brain with the organs of sight, hearing and muscular sensibility would easily explain the vertiginous sensations in disease of any of these peripheral end-organs. While the function of the cerebellum may be that of coördination and the maintenance of "continuous tonic muscular contractions" and while as Spitzka tersely remarks, it may be the center where "impressions of touch and position are associated with those of time and space," I find no authority for assuming that it is in any way the center for the institution of movements or the maintenance of these movements in a regular, methodical manner, which, to my mind, is the underlying phenomenon, objectively or subjectively, of true vertigo. Vertigo is something more than simple incoördination, though incoördination may enter as one of its principal elements. In vertigo there is a disturbance, not merely of the reflex functions but of the higher powers as well. The motor and sensory phenomena of vertigo, in typical cases at least, are not mere sequences of abnormal motor and sensory impulses, but they are the impulses themselves. The distinction which I am endeavoring to make is the same as that between the ataxic movements of

posterior spinal sclerosis and the spontaneous movements of chorea. In the one case there is the retention of power, but the loss of coordination; in the other there is loss of power with or without coordination. Simple incoordination manifests itself in irregular unmethodical movements and thus shows that it is due to an affection of some subordinate regulating center of the brain; true vertigo, like chorea, manifests itself in regular methodical objective movements and thus reveals disease of a higher independent center.

It is a significant fact, when considered in this connection, that the vertigo which is so characteristic of cerebellar disease and which is identical with the vertigo of Meniere's disease, is caused only by lesions in the middle lobe or that part of the cerebellum which is most liable to involve the sensory-motor tract of the medulla; and furthermore, that lesions of the lateral lobes not pressing upon or involving the middle lobe do not give rise to any known symptoms. And it is still more significant that vertigo is not pathognomonic of cerebellar disease, for it may be caused by lesions in other parts of the brain as well. Even in its coordinating function, it is more than probable that the cerebellum, instead of sending out direct coordinating impulses to the muscles, merely coordinates the impulses sent down from the cerebral centers above. Indeed, as Ranney has said, "it is a curious fact that most of the effects of cerebellar lesions are attributable, to a greater or less extent, to irritation of the crura."

According to Goltz, Serres, Cayrade and others, the function of equilibrium is profoundly affected by destruction of the corpora quadrigemina. The experiments of Ferrier upon monkeys, fishes and rabbits, and of McKendrick upon pigeons, revealed the same effects. The corpora striata have also been shown by physiological experiment to preside over the maintenance of equilibrium, especially after the removal of the hemispheres. Every indication points to the fact, then, that we must look for the center of equilibration not in one particular part of the brain, but in the harmonious action of the various sensory and motor centers one upon another.

Now for the application of all this. One of the most common peripheral disturbances of this sensory-motor equilibrium is disease of the ear. Becker has said that "the ear is the most intellectual of all the organs," and in regard to its effect upon the mind, both in health and in disease, it is indeed second in importance only to the eye. Without stopping to consider the many causes of vertigo in connection with the external and middle ear, I will at once consider the question of labyrinthine vertigo. It is pretty generally considered now that only the semicircular canals are affected in *true* Meniere's disease. At least that is what Meniere himself seems to have believed. His second and fourth propositions are that certain functional troubles, having their seat in the *internal auditory apparatus*, may give rise to cerebral symptoms such as intense vertigo, uncertainty of gait, turning to the right or left and falling, all of which may be attended with nausea, vomiting and syncope, and that all this tends to confirm the belief that the lesion which is the cause of these functional troubles is in the semicircular canals. In his original paper he described ten cases, in only one of which was there an autopsy. This case, the tenth of the series, had no disease of the nervous

centers, but the semicircular canals were filled with a "reddish-plastic material." It was on the strength of this single observation that he declared the canal to be the cause of the cerebral symptoms. Aside from the unscientific character of such a hasty generalization, this one case, as Bremner points out, will hardly explain those in which the cerebral symptoms come and disappear rapidly. And if the hemorrhage into the semicircular canals were the cause of the trouble here and in the majority of the apoplectic cases, as Knapp argues, it remains to be shown why the hemorrhage should be bilateral, since the aural symptoms are so frequently bilateral.

Ever since the first announcement of this affection there has been much confusion in regard to it. Disease in any part of the internal ear, and even of the middle ear, has been called Meniere's disease, though, as we have seen, Meniere himself was careful to restrict the lesion, in its apoplectic form at least, to the semicircular canals. Knapp, whose paper upon the subject is second only to that of Meniere himself includes all affections of the entire internal ear, irrespective of their causes, under the name of Meniere's disease. I have examined his cases and fail to see why he should insist so positively upon the inner ear as the source of the vertigo and other cerebral symptoms. In his third case, which he is careful to specify as a fair example of Meniere's disease, one of the most prominent symptoms was diminution of the sight—a condition which remained after many of the other symptoms had vanished. After discussing in full, Voltolini's famous case in which an autopsy revealed an extensive leptomeningitis with pus at the base of the brain, in the pons, medulla and cerebellum, and some hemorrhage into the labyrinth of the ear, he makes the sweeping generalization that "the changes in the nervous apparatus of the labyrinth consequent on the hemorrhage must have been such as to destroy the hearing function forever." Thus he totally ignores the possibility, and in Voltolini's case the extreme probability, of the central injury being the cause of the deafness as well as of the vertigo and other symptoms. In Politzer's case, with autopsy, there was a fissure of traumatic origin at the base of the occipital bone which probably was the cause of the meningitis of which the patient died. Pain at the base of the brain was here a marked symptom. Both Politzer and Lucæ report cases in which the semicircular canals were absent or filled with blood, and yet the patients did not suffer from any disturbance of equilibrium. In the *Lancet* of May 16, 1891, Ferrier reports the case of a man 36 years of age who was stricken with total deafness in both ears after experiencing a sound like an explosion in the head. The ear appeared to be normal, and the diagnosis was hemorrhagic effusion into the labyrinth without cerebral involvement. And yet there seems to have been no pronounced vertigo. In most of the reported cases of Meniere's disease that I have seen, while there was a possibility of the ear trouble being the origin of the special symptom group, there was an equal possibility, and in very many of the cases a strong probability, that the more prominent symptoms were due to a central or medullary lesion, and that the aural symptoms were merely a coincident member of the group.

Gowers, who is one of the strongest advocates of the labyrinthine origin of vertigo, adduces five argu-

ments in favor of his position. His first is based upon the number of cases reported by Meniere and others. I have already shown how inadequate are the proofs from this source. His second is, that irritation rather than mere loss of function in the nerve is proved by the disease being attended with severe vertigo, which may cease when the progress of the disease has produced complete deafness. There is usually so little correspondence between the severity of the vertigo and the amount of the deafness, as Gowers himself remarks elsewhere, that this argument fails.

His third is, that in the majority of the cases of definite vertigo, the slight or considerable tinnitus that is present is evidence of a process of irritation of the fibers of the nerve. That is true, but the argument is no proof of the source of the irritation being within the semicircular canals or labyrinth. Tinnitus is not an unusual symptom of certain extralabyrinthine lesions. His fourth argument is, that slight loss of hearing, tinnitus and vertigo may be observed not only to come on together but to pass away together. I fail to see that this proves anything more about the labyrinthine origin of the vertigo than does the previous argument. Lastly, he asserts that "the frequency with which symptoms of labyrinthine disease are found in cases of vertigo is itself a fact of very great significance. Of 106 consecutive cases in which definite vertigo made the patient seek advice, in no less than ninety-four, ear symptoms were present, tinnitus or deafness, or more often both."

The figures are undoubtedly significant in proving the frequent association of vertigo with auditory symptoms, but they are scarcely commendable as an argument of the labyrinthine origin of the vertiginous sensation. It seems to me, therefore, that these propositions, which I have presented almost in the author's own words, do not make out a very strong case in favor of the labyrinthine origin of the vertigo; certainly not sufficiently so to warrant the large percentage of cases of vertigo which this writer attributes to diseases of the internal ear.

It seems to me, furthermore, that he is almost self-contradictory upon this subject. He lays stress in aural vertigo upon the coincidence of the auditory symptoms with the vertigo, and shows that this is due to the continuity of structure in the cochlea and semicircular canals. He says, "it is conceivable that labyrinthine vertigo may occur without any auditory symptoms. I have actually seen two or three cases in which definite giddiness existed alone and in which auditory symptoms came on later." Then when I turn to his account of gastric vertigo, I find this: "I do not think it is quite certain that there is such a thing as definite vertigo of purely gastric origin. . . . We know that in 95 per cent. of the cases of definite giddiness a morbid state of the labyrinth is the real cause of the vertigo." This leads us to infer, then, that in 95 per cent. of the cases of vertigo there are distinct auditory symptoms. Few general practitioners will be prepared to admit so sweeping an assertion. Would the author have us believe that in the vertigo of seasickness, which is now pretty generally attributed to the disturbance of the visual reflex, there is also a morbid state of the labyrinth? If so, his dictum in regard to the ever-present auditory symptoms does not hold good here.

After admitting the implication of the semicircu-

lar canals in aural vertigo, it still remains a difficult matter to explain the vertiginous symptoms and loss of hearing upon this hypothesis in all cases. The first case which I have reported might easily have been regarded as one of Meniere's disease, and yet there is no reason to suppose that the vertigo and deafness were due to disease of the semicircular canals. I believe that the function of these canals in the maintenance of equilibrium has been much over-estimated, certainly too positively inferred in view of the slight physiological and pathological data which we have as yet for such an inference. Simple puncture of the auditory nerve in rabbits gives rise to rotary movements on the part of the animal, and it is a well-known fact that injection of water into the external ear, as well as inflammation of the middle ear, causes vertiginous sensations. In these cases there is present the sensory-motor disturbance, but can we suppose that in all of them the semicircular canals are so grossly affected as to be the only immediate cause of the vertigo?

Both Steiner and Sewall carefully removed the semicircular canals from the shark, whose auditory apparatus is practically identical with man's, without obtaining any disturbance of movement. The former experimenter believes that the loss of equilibrium results from lesions of the brain or its membrane, causing alterations of pressure, for he has again and again destroyed the canals in sharks, frogs and lizards without injuring the brain, and discovered no disturbance in the power of equilibration. After careful investigation Böttcher and Baginsky have come to the conclusion that the cause of the rotation of the head in Flourens' and Goltz's experiments was the injury done to the brain, and not merely to the semicircular canals. Böttcher marks the fact that the auditory nerve is not bound down at any point between the brain and the labyrinth, and that if one is careful not to pull upon this nerve the vertiginous sensations are not awakened by the injury of the semicircular canals. The slightest traction upon the auditory nerve injures its attachment at the medulla, and so gives rise to the symptoms described by Flourens, Cyon, and Goltz. In the experiments of Böttcher the head, furthermore, did not always rotate in accordance with the particular canal injured, as Goltz had formulated. The identity of these canals with the cochlea in the embryo, their continuity with the epicerebral space through the aqueductus vestibuli, and their ever-shifting relations amongst themselves in the quadruped, which go about sometimes in the horizontal and sometimes in the erect position, argue strongly against the special function of these canals being the maintenance of equilibrium. In the discussion of my paper upon the same subject before the Philadelphia Neurological Society, Nov. 24, 1890, Dr. Dercum reported some observations he had made of the comparative anatomy of the labyrinth for the purpose of securing new light, if possible, upon the function of the semicircular canals. He said: "They bear a distinct relation to the lateral line organs of fishes, the nerve hills of the latter being identical in structure with the macula acoustica. Just as the inclosure of these nerve hills in tubes seems to have for its object the gaining of distinctness and definiteness of impression, so the inclosure of the macula within the semicircular canals seems to have the same object. It is significant that each macula is

situated at the end of a canal, and this suggests that the canal is a kind of conduit to carry off vibrations after they have made their impression on the utricle; and further, that if interference of vibration occurs, it occurs at a point *distal* to the utricle. Confusion of sound is thus avoided. The inference from physiological experiment that these structures have for their special object the maintenance of equilibrium, has always seemed to me open to a serious objection." It is a well-known fact that many fishes have a utricle and three semicircular canals, while some have only one and two canals. Amongst the lowest vertebrates the lamprey has a sacculus with auditory hairs and otoliths in communication with two semicircular canals, while the maxine or hag has only one canal. Doubtless there are important sensory impulses of a special character which pass through these organs, but equilibration, due as we have seen to the fusion of a vast complex mass of sensations pouring in upon the brain from all sides, can not possibly be the result of merely a single set of impulses from such an end-organ as the semicircular canals. The very nature of vertigo involves the idea of more or less loss of consciousness, and this alone would seem to indicate a higher cause for the trouble than simply these canals.

If it be granted that the pathological cause of this vertigo is to be found in the semicircular canals, it is hard to understand how in all cases the cochlea or the cochlea branch of the auditory nerve should necessarily be affected. In Flourens' experiment, the entire removal of the canals did not impair the hearing. So striking was this fact, that Flourens as well as others was led to believe that the branch of the auditory nerve which supplies the semicircular canals subserves motor purposes only. On the other hand, if Gelle's experiments are to be trusted, the cochlea is in no way the source of vertiginous impressions. Simple continuity of structure will not account for the loss of hearing when the lesion is a hemorrhage into the canals, and pressure alone will not answer as a cause in all cases of so-called Meniere's disease. In the first place, there is no regular correspondence between the amount of deafness and the intensity of the vertigo; secondly, with total loss of hearing in Meniere's disease all known methods of diagnosis prove that the nerve itself, and not merely the internal ear, is affected; thirdly, physiological experiment shows that simple pressure does not cause total loss of hearing when no injury is done to the cochlea or cochlea branch of the auditory nerve; and finally, no case has ever been reported in which the cochlea was primarily affected with consequent involvement of the canals and vertigo, though in blood supply and anatomical structure the cochlea and canals are similar. Hence, in Meniere's disease, I conclude that the lesion must concern the whole labyrinth or lie entirely outside of it.

It was Dr. Wilks of England, I think, who held that Meniere's disease was a neurosis of the centers of audition and equilibrium, and in its paroxysmal form at least was much like migraine with its eye complications. While this explanation cannot be adopted for all cases, there is little doubt about the central nature of the disease in many of its aspects. Burnett declared that "the neuropathic diagnosis is well marked in most cases of aural vertigo." The grouping of the symptoms, as well as the proximity

of the tracts of the brain to the centers of equilibrium, indicate a common origin of the symptoms. The disturbance, whatever it is, is a disturbance of the sensory-motor centers of the brain.

Running between the superior and inferior roots of the auditory nerve, at the junction of the posterior division of the inferior root, is the posterior root. According to Spitzka and others, the posterior root transmits sensory impulses, while the anterior root is the path for the efferent impulses that assist in the determination of the equilibrium. Some of the motor fibers of the auditory nerve pass to the ampullae of the semicircular canals, while others are doubtless associated with the anterior root in particular and the peduncle of the cerebellum. Thus the close connection between the nerve of hearing and the sensory-motor tracts in the medulla, as well as the proximity of the auditory and pneumogastric nuclei, account for the frequent association of the symptoms, deafness, vertigo and vomiting. Any disturbance, then, in the course of the auditory tract, such as in the case I have reported, is liable to give rise to Meniere's symptoms. The lesion may assume many forms, but the important point is, that it need not be necessarily limited to the labyrinth. In many of the cases reported the probability is that it was altogether extra-labyrinthine.

In conclusion, I would assert that in Meniere's disease the source of irritation may sometimes be in the semicircular canals, just as sometimes it may be in the eye and in the stomach, but that the immediate cause of the vertigo can not be there for several reasons:

1. If the above explanation of the nature of vertigo be correct, it is a condition dependent upon the inharmonious interaction of the sensory-motor centers of the cortex.

2. If equilibrium depended solely upon the semicircular canals, there could be no rational explanation for the ocular and stomacheal vertigo.

3. If the proximity of the various nuclei within the medulla be a sufficient explanation of the association of the symptoms, vomiting, unconsciousness, vertigo and loss of hearing when the semicircular canals are affected, why, we may justly ask, do we not in stomacheal, lithemic and other vertigos of reflex origin have more frequent and more marked auditory symptoms?

4. Experimental injury to the semicircular canals is not followed by true vertigo, loss of hearing and the other constant symptoms of Meniere's disease.

5. Pathological data do not entirely and satisfactorily support Meniere's hypothesis. His only case with autopsy can easily be explained upon other grounds, and nearly all of the other cases reported by Politzer, Volodini, Knapp and others, and severe cerebral lesions, sufficient to account for the symptoms presented or were unproved by post-mortem examination.

Finally, it is to be noted that of Bezold's carefully collected forty-six cases of neurosis of the labyrinth, only twelve manifested symptoms of vertigo.

Burnett says, "aural vertigo may be termed a reflex cerebral phenomenon from irritation in the auditory apparatus." That may be true as far as it

goes, but, from what I have endeavored to show, aural vertigo may not be aural at all, except only so far as having certain aural symptoms associated with the vertigo; and we are not justified in view of the few physiological and pathological data still at hand, in assigning all cases of vertigo with loss of hearing to an unknown and undemonstrable lesion of the internal ear.

Dr. HENRIE.—I believe that we are approaching a better explanation of the vertigo connected with Meniere's disease as well as vertigo connected with cerebellar diseases. If we adopt the current explanation of labyrinthian vertigo what are we to do with the vertigo from a stomal lesion? What are we to do with vertigo caused by irritation in other peripheral areas and what are we to do in regard to the cerebellar vertigo? Now if you look into the results of therapy in these cases, the history of cerebellar abscess as well as of Meniere's disease in connection with the treatment as it usually suggests itself, you will find that the symptoms of vertigo are very greatly ameliorated and often caused to disappear entirely under judicious treatment to diminish the irritation, of which the author speaks in his paper, which gives us unequal arterial blood supply in all probability. That thing was very forcibly impressed upon me a number of years ago in a case which was reported in a journal of nervous and mental diseases, of cerebral vertigo in which the individual described had the gait characteristic of cerebellar disease, had the vertigo characteristic of that disease and was disposed to walk in a circle after the manner of birds experimented on by Flourens, when he first promulgated the doctrine and gave us the clue to the characteristic symptomatology, or what we supposed to be the characteristic diagnostic symptomatology of cerebellar disease. The first case in which I observed this and the beneficial results of treatment, keeping the portal circulation constantly depleted, the bowels active without fail each day, and putting the patient under bromids, and strychnia, resulted very satisfactorily, the patient was enabled to go about the streets of St. Louis unaccompanied and presented the appearance of a person who was recovered; so much so that his wife believed him recovered, and yet the man actually died suddenly of a rupture into the fourth ventricle, the cerebellar abscess having found its way thither. The case is on record and well known. The first case that called my attention to the fact that it was possible to ameliorate and obliterate the distinctive vertigo of cerebellar disease was this, and yet the cerebellar disease persists and the same has been found true in my experience in regard to labyrinthian vertigo, and I believe that clinical observation confirms the suggestions made by the author in his paper.

ADDITIONAL EXPERIENCES IN THE HYPODERMIC USE OF ARSENIC.

Read before the Section of Neurology and Medical Jurisprudence, at the Forty-fourth Annual Meeting of the American Medical Association.

BY HAROLD N. MOYER, M.D.

Adjunct Professor of Medicine, Rush Medical College; Fellow of the College of American Physicians.

In a former communication¹ we called attention to the value of the hypodermic method of giving arsenic and reported some eight cases all told in which it was employed. Since that time a large additional experience with the method has but confirmed our previous good opinion. The last now

includes twenty-eight cases of chorea, three of paralysis agitans and eight cases of neurasthenia.

The hypodermic use of Fowler's solution has been recommended by numerous writers. Hammond² claimed that the dose which could be administered in this way was much greater than could be safely administered by the mouth. He says:

"I have frequently given as high as 35 drops of Fowler's solution as an initial dose. It is very certain that the stomach would not tolerate this quantity. Again, I have often carried the amount given by the mouth to the utmost bounds of prudence—till the eyes were puffed and vomiting almost incessant—and then have continued the arsenic in larger doses, by hypodermic injections, with the result of the cessation of all gastric symptoms and the cure of the disorder."

Dr. Frühwald treated twenty-two cases of chorea minor by this method. He says that redness of the skin at the site of the punctures was common, and two or three abscesses formed. The dose was from 5 to 20 drops, and after the use of thymol and deeper injections no further trouble was observed.

Grunnack³ treated one hundred cases of goitre with hypodermic injections of Fowler's solution, 1 part to 4 of water.

Dumont⁴ treated twenty-six cases of goitre with injections of 10 minims of Fowler's solution.

It has been noted by former experimenters who have employed arsenic hypodermically that there was a decided tendency toward the development of abscess as well as painful cutaneous inflammation. These writers have invariably employed Fowler's solution and its irritating effects were attributed by some to a septic condition of the solution and by others to the spirits of lavender used to color it. Prof. W. S. Haines suggested that the irritating properties of Fowler's solution when injected into the cellular tissue was probably due to the free arsenious acid usually contained in the preparation as found in the shops, and that these might be obviated by using the arseniate of sodium, a stable salt, readily soluble and of definite composition. Dr. Haines recommends that the pure anhydrous salt be used; as ordinarily found in the shops it may contain from four to twelve molecules of water of crystallization. If this be driven off by heating to 300 degrees the resulting salt has a definite composition with the formula $\text{Na}_2\text{H}_2\text{AsO}_4$; a 1 to 100 solution of this salt contains 53 per cent. of the arsenic found in Fowler's solution, so, approximately, the dose of such solution should be about twice that of the liquor potassii arsenitis.

Arsenic is one of the peculiar and exceptional remedies that is much less poisonous when exhibited beneath the skin than when given by the mouth. The reason for this is shown by the fact that arsenic like several metallic poisons focuses itself largely about the upper end of the small intestine, stomach and liver, and toxic symptoms even if the arsenic is given in large doses under the skin will not appear largely in those organs. Thrown into the cellular tissue it is at once absorbed into the general circulation and is distributed to all parts of the system, while if given by the mouth it may make the rounds of the portal circulation several times before entering the general circulation. It is this peculiar fact that makes arsenic

¹ Nervous Diseases.

⁴ Carr. Bl. für Sch. Ärzte.

treatment. I think in a large majority of cases that time alone will effect a cure; I will not say despite the arsenic, but I will say that time and rest are the essential remedies, and those remedies which conduce to rest of the central nervous system are the important factors; that is why we get cures from chloral given every night and in the daytime as some of our German friends do. That is why you get it from giving the child a vacation, taking it away from school, giving it a change of scene. One of my patients was cured within the last six weeks on a very simple prescription. The child took a vacation and went off to Texas and got well by traveling.

THE CHAIRMAN—I would call attention to the fact that the principal point of this discussion is the hypodermic use of the arsenate of sodium.

DR. FRANK R. FRY, of St. Louis—I think the doctor has fully demonstrated the advantage of his method. I have used the arsenic hypodermically, though I have never used Fowler's solution in that way, but a solution of equivalent strength made aseptically, and I have had a great deal of irritation from it, though I have never had an abscess, but so much irritation that I have abandoned it long ago in the majority of cases, only occasionally employing it when the stomach was absolutely intolerant; and therefore I can corroborate the statement that the doctor has made that it is not the aseptic properties nor the irritating properties of the lavender water or spirits of lavender in the solution that make it irritating, but the salt itself. Furthermore, in having these solutions prepared I was always careful to get a chemically pure salt.

DR. ELMORE S. PETTYJOHN—These cases are usually found in young persons, and there might be a great deal to overcome in giving these injections. How does the doctor manage that matter to the satisfaction of his youngest patients?

DR. MOYER—I regret, since the discussion has taken the range that it has, that I have not here to present to you some of my clinical histories. I did not at first desire to burden this Association with an account of a lot of choreic patients. I conceive that we all see a vast number of them; but I will say to the gentleman who first made some inquiry that I have treated inveterate chorea and the recurrent chorea and chorea in its chronic forms, and I have treated acute chorea in fact all varieties by this method. Of course the value of any therapeutic measure depends upon the experience of the man that proposes the method, and I can not bring you anything to support it more than my individual assertion. I have treated 500 cases with arsenic given by the mouth and 28 by this method, and I am absolutely surprised and amazed at the results that I have obtained. I certainly think that the average duration of treatment has been very much less than six weeks. I do not think that under this method it has averaged over two weeks. I fully agree with Dr. Hughes regarding many things in the treatment of chorea. It is a self-limited disease; it is a disease whose natural tendency is to get well whether you employ treatment or whether you do not; the patient will get well in the great majority of instances, but I contend that in my experience, specific treatment is useful, and of all methods arsenic is by far the most useful and of all the arsenic methods the hypodermic use of the drug is the best. You can get a much larger quantity into the patient's system without any toxic effect, and you produce a very profound impression indeed, and it has not been an infrequent occurrence with me to have the choreic movements lessen or cease entirely within three days. I understand that there are a great many hygienic measures that can be employed in the treatment of chorea in the better class of patients, but the majority of my cases are

out patients in a large dispensary, seven to fifteen years of age, the disease rarely affecting those below the seventh year, and I have been wholly unable to control their diet, and habits of living; many of them are children employed in factories and shops, belonging to the lowest classes in a large city, and it is among this class of patients in which you can do nothing for them except what you do medicinally that I would above all things recommend the trial of the hypodermic use of this drug.

Regarding Dr. Pettyjohn's question, I would say that the patients perhaps object to it—the little ones do—those that are eight or ten do not seem to care very much. The younger ones you simply take by the arm, the mother holds the other hand, and you give them the injection; that is all there is to it. If they cry a little, why let them cry; but as a rule I have not found much difficulty in giving injections, even in quite young children. The slight prick may be objected to at first, but after one or two injections they generally do not care very much about it.

THE FUNCTION OF THE RIGHT TEMPORO-SPHENOIDAL LOBE.

Read before the Section of Neurology and Medical Jurisprudence at the Forty-fourth Annual Meeting of the American Medical Association.

WM. J. HERDMAN, Ph.B., M.D.

ANN ARBOR, MICH.

In an authoritative work on "Diseases of the Nervous System" recently published, the temporal lobe of the brain on the right side in man is spoken of as one of the "latent regions of the brain, destruction of which, and irritation of which, produce no special or distinctive phenomena." Clinical and pathological evidence bearing upon the functions of the temporal lobes is acknowledged to be scanty at present by no less a specialist on this subject than David Ferrier; and the discrepancies in the results of the many experimental researches upon animals conducted by him, Victor Horsley, and other observers of undoubted merit, cause us to welcome any additional light, however meager, that will aid in clearing up the darkness that still surrounds this region of the human brain.

A most novel and interesting case recently came under my observation in consultation, which terminated fatally within five weeks from the beginning, and in which I had the good fortune to obtain an autopsy, that may in some small degree add to existing knowledge as to the part taken in cerebral action by the right temporo-sphenoidal lobe.

Mrs. G. E., a native of Michigan, 45 years of age, spent the greater part of her life on a farm and was always a hard worker. Her constitution and general health had always been good although she was not robust. She has given birth to two children the younger now being 15 years of age. A few years prior to her last illness she consulted an oculist for a slight impairment of vision in the left eye but it never gave her much trouble. She never had rheumatism, gout, syphilis, cancer or any other serious disease or injury, but she has been a sufferer from headaches for many years. Her father died suddenly, presumably of heart disease in some form. Two of her uncles have died of brain trouble and a sister has epilepsy-graviter; two sisters are subject to severe headaches. Her habits and modes of life were always exceptionally good and regular and her hygienic surroundings were always of the best. She was of a lively and sociable disposition, active and efficient in her circle of acquaintance and much employed with church and Sunday school work. About five years ago she changed farm life for village life and has for four years successfully managed the finances of a moderate estate which devolved upon her at the death of her husband.

On April 3, 1893, while about her household duties she felt

dizzy and sick at the stomach, and she stated to her son who came into the house soon after and found her lying on a couch, that she had fainted in the kitchen and after regaining consciousness which could have been absent but a few moments, she had without assistance walked into an adjoining room and laid down on the couch. While talking with him she had what seems to have been a spasmodic seizure and again became unconscious. Her physician was summoned who on arriving within half an hour found her with all muscles relaxed except the inferior recti which seemed to be contracted. The heart's action extremely feeble. Ammonia carbonate was injected hypodermically and effluvia of amyl applied to the nostrils. In about twenty minutes some signs of improvement were noticed in the circulation and at the end of three hours the pupils returned to normal condition. She would then swallow liquids placed in her mouth if requested to do so by speaking loudly close to the ear (right).

There was no motor paralysis attending or following this condition for she freely moved both arms and legs, and there was no disturbance of the facial expression, but the intellect was profoundly clouded.

April 4.—Spent a restless night, respiration moaning and sighing, with an occasional exclamation of "Oh dear," but no satisfactory response could be gotten to the inquiries as to the cause of her distress. Temperature 101, pulse 100.

April 5.—Slight improvement in the intellect but still unable to recognize those about her. Kept carrying her hands to her head and exclaiming "Oh my head," at frequent intervals. The distress in the head seemed to be constant and mainly over the left frontal region. She took nourishment when it was given to her but gave no sign of recognizing the need of it. Very restless, tossing herself about in the bed. Temperature and pulse the same as the day before.

April 6.—Some improvement; answers when spoken to but often irrelevantly. Complains of severe pain in frontal region. Temperature 100, pulse 94.

April 7.—Further return to consciousness; calls friends by name but with some hesitancy. Seemed to have no memory of what had happened and expressed surprise when told she had been sick; said if it were not for her headache she would be quite herself again. Headache constant and frontal; other symptoms remain unchanged.

April 8.—No change; still restless and severe headache.

April 9.—Headache less severe, mental conditions still further improved, more mental activity but attacked by hallucinations; able to recognize friends. Temperature and pulse normal. She was given a dose of castor oil which ordinarily was extremely disagreeable to her and swallowed it without remark. In health the taking of castor oil was a thing she declared she could not do. Afterwards when reference was made to it, she remarked that she must have been very sick if she took castor oil and did not complain of the taste.

April 10 and 11.—Headache less acute and constant; mind clearer; she called to mind events that had occurred and began to take interest in the household duties; still troubled with hallucinations, but they were of a pleasant type and she laughed when relating them.

At this time it was noticed that, although her mind had regained its activity, hearing on the left side was dull and confused; as she expressed it she "heard double."

April 12.—Began to sit up a little; headache not constant. Hallucinations of being away from home, out in company and having a good time.

April 13, 14, and 15.—Very little change except gradual improvement; less aberration of the mind. Sat up a good portion of the day.

April 16.—All pain in the head gone; mind clear and she felt quite like herself; got up and dressed and was about the house all of the day. Much pleased at the visits of her friends. Laughed and joked with them and they could not see but that she was quite well. She took her meals at the table with the family. With the exception that her hearing was imperfect especially upon the left side, and the taste remained blunted, there was at this time no evidence of sensory, of motor or mental disorder.

This marked improvement continued until April 22. She planned to resume her household duties and discharged all attendants and appeared quite like her natural self. No abnormality in mental action or in movements was observed by anybody about her.

April 22.—The attending physician was again summoned; found her complaining of much frontal headache. The temporal arteries were distended, but there was no abnormal

action in the pupillary reflexes, nor was there any confusion of the mind. He was again summoned on the night of the 23d and found her unconscious, respiration slow, pulse feeble, pupils normally dilated. No marked spasm of any muscles. Cardiac and respiratory action soon improved and after a few hours she could be so far aroused as to be induced to take liquids and swallow them.

April 24.—Still comatose but could be aroused somewhat by loud talking. Temperature 101. Pulse 96; respiration 24.

April 25.—Condition unchanged except the coma was not so pronounced. She would often carry her hand to her head exclaiming, "Oh my head."

April 26.—Condition much the same, except at intervals she recognized members of the family about her.

April 27, 28 and 29.—Gradual improvement in the mental conditions, intellect sluggish and unable to fix her mind for any length of time upon any subject. Eyesight normal with the right eye but with the left unable to count fingers at a distance of twelve inches. Complained of much headache and some pain in the base of the brain; took abundant nourishment.

In the afternoon of April 30, the nurse discovered that the left side was paralyzed throughout, the facial muscles and the tongue being involved; she was unable to turn the left eye outward. Involuntary actions of the bowels and bladder.

May 1 and 2.—Remained the same; speech and swallowing imperfect. The patient was left handed.

May 3 and 4.—Improvement in speech and swallowing, and began to get voluntary control of the left arm and leg.

May 5.—Respiration normal; some voluntary control over the action of bowels and bladder regained. Still some disturbance of speech and deglutition and the face remained slightly drawn to the right. The tongue when protruded turned to the right, was red and clean. Vision much improved in left eye and right eye normal. Left eye cannot be turned outward; mental action dull, but able to recognize friends. Thoughts disconnected and disjointed. She was able to sit up in bed for a few moments and to move from one side of the bed to the other.

May 6.—Continued to improve. Took nourishment readily. Strength in right arm and hand increased. She was able to grasp the hand of the nurse quite firmly. Eyes normal in appearance but the left still impaired in action of external rectus. Vision unchanged. The temperature on this and other days after April 30 did not exceed 99.2. Speech was now quite distinct. Mind clear but inactive. Headache which had been light returned with great violence towards evening.

May 7.—Passed a restless night, manifesting more than her usual timidity. Clung closely to the nurse. Had several general convulsions in the morning from 8:30 to 9:30 during which the left eyelids were open and the pupil contracted. The pupil of the right eye was widely dilated, the lids closed. The headache seemed very severe as evidenced by her moaning and carrying her hands to her head after the convulsions ceased. Stupor followed the convulsive seizures and gradually deepened into coma, though consciousness was retained long after she was able to utter a sound. Hearing was not abolished up to within an hour or two of death for she would squeeze the nurse's hand in response to inquiries uttered in a loud tone; but she lay upon the bed in such a manner that she could not be approached only upon the right side, and hearing upon the left side was not tested during the last weeks of her illness.

NECROPSY.

Eighteen hours after death. Skull unusually thick. Dura mater congested and apparently thickened. Superior longitudinal sinus empty; venous congestion of the pia mater; the arteries moderately full. No naked eye appearance of special abnormality about the frontal lobes, although the anterior cerebral arteries seemed somewhat more anemic than others. A clot of dark semi-coagulated blood about two inches in diameter occupied the right middle cornu, and the walls of this cornu were extensively disintegrated and readily gave way. The disintegrated tissue involved the anterior half of the hippocampus, the anterior extremity of the superior temporal and the anterior third of the middle and inferior temporal gyri. The gyrus hippocampus was largely undermined although its surface remained intact. The island of Reil was softened. Blood coagula, more or less firm and recent in formation, filled the lateral ventricles, the third ventricle and the infundibulum, and extended through the aqueduct of Sylvius into the fourth ventricle. No softening or disintegration had taken place

except in the right temporo-sphenoidal lobe. The time being limited other cavities of the body were not explored.

I need scarcely say to you who have been able to follow me in this hurried recount of bedside observations, that the revelations of the autopsy were something of a surprise to me. In the light of the discoveries then made I was compelled to admit to myself that I had, in constructing a theory of causation of the clinical phenomena observed, placed too much stress upon certain prominent symptoms. I saw the patient twice for about half an hour each time. On the first occasion, the suddenness of the onset of the symptoms; the mental confusion; the severity of the headache, which was frontal and left-sided; the impairment of vision of the left eye; the entire lack of motor and sensory abnormalities (for this was at a time when she was beginning to recover from the first attack) impressed me quite forcibly, and I was confident there was an arterial embolus obstructing the left anterior cerebral artery. The subsequent complete clearing up of the mental cloudiness and the subsidence of all other symptoms only confirmed me in this opinion. The only thing that was suggested to my mind that threw doubt upon this conclusion was how to account for the dullness in hearing in the left ear. But in the apparent harmony of the more prominent symptoms in accord with my theory, this did not seriously attract my attention. The perverted or impaired taste was not an observation of my own, but was a fact learned from inquiry of the attendants subsequent to the autopsy. The theory of embolism seeming to account for the symptoms following the first attack, the phenomena attending the second attack, which occurred after twenty days, and when many of the disturbances resulting from the first had subsided, presumably because of some degree of collateral circulation being established, were accounted for on the assumption that a thrombus had formed posterior to the embolus and its backward growth had, in all probability, crossed the anterior communicating artery and suddenly plugged the other anterior cerebral, as at this time, you will observe, there were no spasms, no paralysis, simply an obscuring of mental faculties which again largely cleared up within a few days.

The autopsy revealed that the original attack had been due to a hemorrhage, not very extensive, inferior to and at the lower extremity of the right lateral cornu. Softening followed, involving the hippocampus major at its lower extremity, the anterior extremities of the superior middle and inferior temporal convolutions.

The hemorrhage from its location might have caused pressure on the optic commissure, especially its left side, together with interruption in the circulation through the anterior part of the circle of will in rendering the anterior cerebral arteries anemic. At the second attack the hemorrhage, still more extensive and far reaching, had extended into the lateral ventricles and the third, even passing into the infundibulum and distending it, causing pressure on the pituitary gland. The third attack, from which she never rallied, was attended by an escape of blood from the same source, but in addition to flooding the lateral and third ventricles it had passed through the aqueduct of Sylvius into the fourth ventricle.

I think we are justified in the assumption that as far as any symptoms observed in this case can be

justly referred to the lesion in the right temporal lobe, they tend to show that its function is of the same nature for the left side of the body that Ferrier has found the left temporal lobe to be for the right, a cortex center for hearing and taste.

My experience in this case has impressed upon me more strongly than ever the necessity of a systematic and thorough examination in detail of all the sensory and motor tracts in every case of central lesion, and that according to a definite plan should, wherever circumstances permit be rigidly carried out, even through certain symptoms may seem to show that such extended investigation is superfluous.

DR. KIERKSA—As Dr. Herdman has indicated in the first part of his paper, it is well known that lesions of the right temporal lobe give fewer special symptoms than lesions in any other part of the brain. It is in some respects the almost latent region of the entire brain. Doubtless it has its functions. The doctor has suggested in his paper that the functions of the right temporal lobe are the same for the left side of the body as the left for the right, but the functions of the left temporal lobe, at least the principal part of the left temporal lobe, are largely for hearing, which is not a function for either the one or the other side of the body, and in many cases the left half or left side of the brain in certain functions, acts for both sides of the body. It is interesting, however, in this case, to note that the patient was left handed. Now, ordinarily, I have no doubt, that while the right third frontal convolution and the right upper temporal convolution and the temporal convolutions generally are comparatively latent, yet they are centers for these functions potentially, before the left side of the brain is developed. Here it would seem to me to be the reasonable explanation that probably both the right third frontal and the right upper temporal, in accordance with what we find in left-handed cases, had taken on the functions of the left side of the brain more largely than is usual. I have had several cases of lesion of the right temporal lobe. One of the most interesting cases that I have ever seen is recorded in my paper on cerebral localization, and it was also reported by Dr. H. C. Wood, whose case it was in fact. It was originally a case of tumor of the right temporal lobe. This tumor grew and radiated in various directions. Finally hemianopsia and other symptoms indicative of lesion of the occipital lobe were present, and then Dr. Wood in consultation with ophthalmologists and Dr. Agnew, decided on an operation, and the patient was trephined over the occipital lobe of the right side. The patient latterly had lateral hemianopsia. Dr. Agnew came down on really a radiation of this tumor, but doubtless that which produced the hemianopsia. The patient died; an autopsy was made. I saw the specimen which was an immense tumor involving the entire right temporal lobe, or very nearly so, and thence had grown backward into the occipital lobe. There was a record of observations of this patient for a long time which showed that this tumor had been in the lobe with some development for a long time, but the practical point about it was that the lobe usually, so far as we know, is latent in symptomatology and that both neurologists and surgeons should pay very strict attention to the possibility of symptoms indicative of occipital or other lesions being really the symptoms of the final development of a right temporal lesion. I had one other case which I have also reported; a glioma of the right temporal lobe, the patient dying from intercurrent hemorrhage.

LAWS OF GROWTH OF BACTERIA APPLIED TO ASEPTIC SURGERY.

Read before the Section of Military Surgery, at the Annual Meeting of the American Medical Association, September 7, 1892.

BY ROBERT REYBERN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY, SCHOOL OF MEDICAL SURGERY, UNIVERSITY OF MICHIGAN, ANN ARBOR, MICHIGAN.
HOWARD UNIVERSITY, WASHINGTON, D.C.

It has been well said by a great operator that every surgical operation is a study in bacteriology. There will be found, we believe, at the present day very few surgeons who will gain-say the above statement, and yet it may be worth our while to examine the question whether our surgery, as practically carried out, is in perfect accordance with the laws of bacterial growth which are the underlying basis upon which aseptic surgery has been built. To return to elementary principles: let us inquire what are the three essential conditions favoring the growth of bacteria and other microorganisms? The answer, of course, that would be given by every tyro in surgery would be the well worn statement: heat, moisture and atmospheric air. In other words, the very same conditions which favor the growth of bacteria are precisely the same conditions that are essential to the growth and repair of all the tissues and organs of the human body.

The logical sequence of this results in the following statement, viz: That no treatment of the tissues or organs of the body involved in surgical operations can be successful, which seeks by the action of powerful chemical agents to destroy bacteria in and around wounds; for if powerful enough to accomplish that object, the tissues themselves must be destroyed or injured.

A surgical operation is to a certain extent the opprobrium of medicine, for in having recourse to it we thereby confess the failure of our science. The ideal surgical operation, therefore, is one that removes the diseased or injured portion of the body with as little disturbance of the normal conditions of the tissues as possible. Repair without inflammation is, as all know, the motto of modern surgery. How preposterously absurd, therefore, is it for us, after having removed, let us say, a tumor or limb from the body, to douche the seat of the operation with solutions of mercurial chlorid or other powerful irritant, producing necrosis of the tissues and thus preventing the very end we seek to attain.

Notwithstanding the profound respect that all surgeons feel for the work and self-denying labors of Sir Joseph Lister, yet there can be no questioning the fact that the theory and practice of antiseptic surgery are rapidly being abandoned, and the more perfect science and art of aseptic surgery are being substituted in its stead.

To Prof. Lister we owe the grand idea of excluding the bacteria and other germs from wounds, thus creating the new science of antiseptic surgery. It is perfectly true that aseptic surgery, as now practiced in this country and in Europe, is very different from, and far superior to, the cumbersome procedure and dressings devised and practiced by the father of antiseptic surgery. The carbolic spray, once universally applied, has been almost entirely abandoned, and during my recent visit to Europe I never saw it once used. The many layers of protective gauze, mackintosh, etc., are now replaced by a single layer of iodoform gauze, with an abundant layer of aseptic cotton firmly retained by bandages.

Another remark, made at the meeting of the American Medical Association, in 1892, was that the use of mercurial chlorid as a germicide was without warrant, and has been shown to be without warrant. The same may be said of the use of corrosive sublimate, and the other solutions of mercuric compounds. Mercuric chlorid has been used as a germicide, and sheet anchor as a germicide. As a germicide, it is one germicide after all, it never kills, it never kills, and rely on that. Yet the germicide is not the work of tearing down, it is the work of tearing down, they have not left us this. Recently, St. Louis, carried on at Johns Hopkins University, operated in the Johns Hopkins Hospital, on April 1891, pp. 50-60, by Dr. A. C. Adams, and Corrosive Sublimate as a Disinfectant against Staphylococcus Pyogenes Aureus, on page 59, at the end of a very elaborate series of investigations on this subject, he says: "It is seen that under the most favorable conditions, a given quantity of corrosive sublimate has the property of rendering inert only a given certain number of individual organisms." (Ibid, page 60, he summarizes his results in the following words: "In the light of these experiments and those of the experimenters quoted in this paper, it is plain that for use in surgical practice, the solutions of corrosive sublimate do not possess all of the advantages hitherto attributed to them. The employment of the sublimate solutions upon wounded surfaces is plain there exist at least two serious objections: First, the albumen of the tissues and fluids of the body tends to diminish the strength of or render entirely inert, the solution employed; and second, the integrity of the tissues is materially injured by solutions of this salt."

Investigations made at the University of Michigan (published in the *Medical News* of October 1 and 8, 1892), have shown that solutions of mercuric chlorid when used as a germicide are often inert, and still often actually injurious to the tissues when applied during surgical operations.

Dr. Charles T. McClintock gives in the above paper (*Medical News*, October 8, 1892, p. 399), the following summary of his experiments, viz:

"1. The high rank heretofore given to corrosive sublimate as a germicide is without warrant and was based on faulty experiments.

"2. The very varying power of resistance in different cultures, as pointed out by E. March and insisted on by Gruber, is an all important factor to be noted in determining the germicidal power of any agent.

"3. That sublimate forms with cellulose, as with filter-paper, etc., with silk, with albuminous bodies, with some part of bacteria (probably the envelope, a chemical compound that can not be removed by any amount of washing with water.

"Thus the sublimate, when acting upon a germ, forms a capsule around it that protects the germ for the time from the further action of the sublimate, and in turn forms an impenetrable barrier to the growth of the organism unless it be removed. This barrier may be removed with salines, and is more rapidly removed in proportion to the renewal of the salines, conditions that are fulfilled in the circulating blood.

"The above named experiments would seem to warrant the expression of the opinion, that the use of solutions of corrosive sublimate in surgical operations should be limited to the clearing of the sur-

face of the part to be operated on, and to the disinfection of the hands and arms of the surgeon; and furthermore, that such solutions should never be applied to surfaces denuded of epithelium, or cut surfaces of the body made during surgical operations."

Antiseptic surgery endeavors to destroy the micro-organisms in and around the wound, and thus prevent their development. How futile this effort must be, when we consider that these organisms are everywhere and at all times present with us. They are in every breath we draw, in much of the water and in many of the articles of food that we consume; and indeed, exist always in the alimentary canal and all parts of the body exposed to the air. But on the other hand, it must be remembered that there are bacteria and bacteria. There are some species of bacteria which, when planted in a wound, will bring forth as the result of the poisonous materials formed by them, the formation of pus with the resulting septic fever, as certainly as the acorn when planted and nourished will develop into the sturdy oak. There are other species which when they come in contact with a wound are practically harmless. Of course we can not with the naked eye distinguish between the poisonous bacteria and the harmless ones, and hence our only safe plan is to as far as possible exclude them altogether from wounds, whether made by violence, or those made during surgical operations. How, then, can this be done? The first point to be observed is, to use as little water or watery antiseptic solutions as possible in contact with the wounds made during surgical operations. The reason for this course is that by so doing we remove one of the essential conditions necessary for the development of bacteria, and thus prevent or at least hinder their growth.

It is practically impossible to diminish or prevent the growth of bacteria in a wound, by either raising or lowering the temperature of the wounded parts; hence we can only endeavor to accomplish this object by making use of the other two methods of limiting bacterial growth, viz: to keep all wounded surfaces as dry as possible, and exclude them from the action of the atmospheric poisonous germs during the process of repair.

Simple and self obvious as these principles of treatment may appear to be, yet they are largely neglected and ignored by very many surgical operators at this very time. Often during an operation performed even by a most eminent surgeon (let us say an amputation), we see the field of operation deluged with a solution of boric acid, a solution of carbolic acid, or worse still a solution of mercuric chloride. This seems to be radically wrong in practice and entirely inconsistent with the elementary principles of aseptic surgery. Of course, in operations which require the opening or removal of large suppurating cysts or cavities, it is necessary to wash them out. This should be done, we believe, with fluids as near the composition of blood serum as possible. That wonderful operator, Lawson Tait of Birmingham, England, who has nearly completed his third thousand of operations upon the abdominal cavity, uses no fluid to wash out the abdominal cavity during his operations, excepting recently boiled water.

For use in surgical operations the following fluids only are necessary, viz: recently boiled water used tepid (about the temperature of 100° F.) and normal salt solution (0.75 per 1000) easily made by dissolving

one ounce, avordupois, of common salt in a gallon of boiling water).

Aseptic surgery therefore, after all is nothing but cleanliness, but when we say that, we mean cleanliness carried to a microscopic degree of perfection, and far surpassing the ordinary ablutions by soap and water. What we endeavor to do at the present time, before any surgical operation, is to so thoroughly cleanse the patient, the surgeons, assistants, nurses, surgical appliances and dressings (of course including the hospital and all its surroundings) so that no germs of poisonous bacteria can infect the wound, and cause suppurating fever, and perhaps the death of the patient operated upon. Modern surgery starts out with the assumption that in an operation aseptically performed upon an aseptic patient, and by an aseptic operator, there should be neither suppuration nor fever following any surgical operation. This of course is the ideal of surgery, which can not always be realized, but nevertheless it is the goal towards which we should aim, and which we should always endeavor to attain.

Every instrument and surgical appliance must be sterilized shortly before the operation, either by boiling in water containing 1 per cent of carbonate of soda (commonly called washing soda) half an ounce to three pints of water, or by being exposed to a dry heat above the temperature of boiling water (from 230 to 240 degrees Fah.) for one-half hour before the operation.

This can be done in the various patterns of steam and dry sterilizers which are now on the market, and can be procured at a moderate cost. But my principal object in writing this article is to call attention to the fact that aseptic surgery can be practically carried out without the purchase of any apparatus whatever. A tin wash boiler, which can be found in the humblest home is just as good for sterilizing surgical instruments as Arnold's, or other of the steam sterilizers now in use. A still more simple sterilizer for small instruments is the ordinary oblong tin baking pan, so familiar to our eyes in our youthful days. This pan when filled with boiling solution of carbonate of soda, may not look quite so ornamental as a porcelain evaporating dish, or a forty dollar copper sterilizer, but it will do just as good work. As before mentioned, to the above must be added absolute cleanliness of the operator, assistants, nurses, and in fact of all who come in contact with the patient. It is scarcely necessary here to say that the part operated upon, and the arms of the operator, assistants and nurses must be thoroughly scrubbed first with soap and water, and then with solution of one to 2000 mercuric chlorid, just before the operation.

One incidental and very great advantage in operating in private houses, providing they are clean and in good sanitary condition, is that the germs of poisonous bacteria are for obvious reasons not so liable to be found there as in the air of crowded hospitals. In regard to the sterilization by the dry method, the only thing that is absolutely necessary to be purchased is a good thermometer, graduated to a temperature of 300 degrees Fah. Of course it is convenient, and perhaps more surgical looking to buy a dry sterilizing apparatus, but it is by no means essential. The oven of a kitchen range or that of an ordinary cooking stove will answer every purpose. Take a common pasteboard box, such as letter

envelopes are packed in, place in the bottom of it a layer of aseptic cotton about two inches in thickness, lay on this your instruments and surgical appliances (bandages, etc.) with your thermometer, and your apparatus will then be complete. Place in the oven and expose to a temperature of 230 to 240 degrees Fah. This temperature can be easily regulated by a little practice, and is lower than the temperature required for ordinary baking purposes, which is said to be 270 degrees Fah. Finally, allow me to add the following maxims: 1. Never use a drainage tube in a wound unless you are absolutely certain you can get union by first intention. 2. If you have an amputation to perform, ligate every vessel requiring it with aseptic catgut, silkworm gut or silk; cut the ligatures off close to the vessels and leave them in the stump, close the flaps with similar sutures, and use no adhesive plasters in contact with the flaps of the stump. After you have stitched up the flaps, dust their surfaces with iodoform, boric acid, or subnitrate of bismuth. Place over this a layer of iodoform gauze, then an abundant layer of aseptic cotton, and over all this two layers at least of a well-fitting bandage. The reason why I do not use adhesive plaster in contact with the flaps of the stump, is that it can not be properly sterilized, and is very often the means of infecting the stump.

Above all things, never open a stump for ten or twelve or even fifteen days after an amputation, if the temperature of the patient is at normal point, or even a degree above. The last limb I amputated was dressed for the first time on the sixteenth day after the operation. On the other hand, if the temperature goes up to 102 or 103 degrees, open up the stump at once, and find out the cause of the trouble. In Bichat Hospital (located in Paris, France), I saw a number of stumps of amputation in the summer of 1892 which had only received two dressings, one on the fifteenth day; and the other final dressing on the twenty-eighth day after the operation.

ADDRESS.

CHAIRMAN'S INTRODUCTORY ADDRESS.

Read before the Section on Ophthalmology at the Forty-fourth Annual Meeting of the American Medical Association.

BY S. D. RISLEY, M.D.,
PHILADELPHIA, PA.

I can not refrain from expressing my high appreciation of the honor you have conferred in calling me to preside over the deliberations of the section. Permit me to extend my most cordial greetings and to express the personal gratification I feel in again meeting my colleagues in ophthalmology from all sections of our country. It is fitting that I should congratulate the section that its members have again been spared through the toil and vicissitudes of a year and are still actively engaged and deeply interested in this beneficent work. The activity displayed everywhere as set forth in a rapidly growing special literature is encouraging, not to say inspiring. Not only are periodicals devoted to ophthalmology multiplying, but the character of the papers published are rapidly improving. Careful scientific work is obviously on the increase and the clinical papers also portray a class of work far superior to that of only ten years ago. To me this has been a source of great encouragement and to us all just cause for

congratulation. There can be no question as to the large share the members of this section of the American Medical Association have had in this advance. It is my ambition to see it assume the role of authority in our special work in the United States, so that its utterances shall be regarded as the expression of the latest and best opinions. In uttering this sentiment I am sure that I but voice the feeling of every member of the section. If this ambition is to be realized, however, to any higher degree than in the past, it must be through the unselfish devotion of every member, not only in his everyday individual work in laboratory and library, clinic and consulting room, but devotion also to the interest of the section. While I have no doubt this feeling of devotion has been entertained by every member, our methods of section work have not afforded adequate means for its expression. The fault, if any, has been in a lack of careful organization. There has been no lack of material; indeed, we have been overwhelmed with the abundance presented for consideration and discussion, but we have been too prone to content ourselves with the simple recording of the facts of our experience. Paper after paper has been presented, manifesting the most painstaking and interesting observation of unusual experiences. Some discussion has followed or similar experiences have been doubtfully reported from memory, thus adding to the richness of material, but in the end much loss has been sustained, both from want of time for adequate discussion and from the want of classification of reported facts. I fear I shall take too much of your valuable time by attempting to present this in all its bearings, so content myself with the statement that our design should be, first of all the presentation of the carefully prepared papers, and for this the greatest latitude should be accorded. To adopt any method which would hamper this feature of our work would, I am sure, be a great mistake. But in order to secure the highest usefulness it would be of great service if each member should study the list of expected papers and prepare for the discussion by reviewing his own experience in the same direction. By this means we would secure a consensus of opinion and the section speak as a body in its transactions, instead of presenting simply collections of individual views as expressed in the published papers. In the second place, special provision should be made for the elaborate study of some special topic or some form of disease which has baffled our skill or about which there is diversity of views as to nature and treatment. For this purpose I would suggest that at each annual meeting a commission should be appointed for the investigation of some selected subject, to report at the following annual meeting. By way of illustration, who of us would not like to have the report of such a commission, e.g., hemorrhagic glaucoma or retrobulbar neuritis, or the pathogenesis of the myopic eye, or the nuclear palsies of the ocular muscles, or the anomalies of ocular balance. Then a carefully organized discussion of the report of the commission would secure a valuable review of the subject and the consensus of opinion of the section, which would find place in special literature, be widely quoted and the reputation of the section and of American ophthalmology be greatly increased. Such studies would render the sessions of the section so valuable that

none of us could afford to miss its annual meeting and thus the prosperity of the section would be generally enhanced. In the publication of our special bound volume I would suggest that the discussion should also be included so that any unusual views presented by the author of a paper should stand in juxtaposition to the expressed views of his colleagues.

PANNUS AND ITS TREATMENT BY THE DIGESTIVE FERMENTS.

Read in the Section of Ophthalmology, at the Forty-fourth Annual Meeting of the American Medical Association.

BY JAS. A. LYDSTON, M. D., Ph. G.

Formerly Professor of Inorganic and Medical Chemistry and Lecturer on Diseases of the Eye and Ear, Chicago College of Physicians and Surgeons, Chicago, Ill.

The etiology and course of pannus are so fully appreciated that it will not be necessary to consume valuable time by entering into a lengthy description of the disease; suffice it to say for the purposes of my paper that inasmuch as pannus is one of the most frequent sequelæ of trachoma I shall limit my remarks to the so-called granular pannus; that is, that form in which the formation of granular masses in the corneal layers has caused infiltration and vascularity of the corneal surface.

In this type, the morbid changes first begin to assert themselves in the upper margin of the cornea at the limbus conjunctivæ and we note further that its tendency to clear is in direct proportion to the degree and duration of the inflammatory process; in other words, the further the process departs from the character of a simple infiltration throughout the more ominous will be the prognosis and, indeed, in the light of our present knowledge bearing on this subject we know that complete reparation after pannus which implicates the deeper corneal layers is a forlorn hope; but in all cases in which the cell migration which constitutes the infiltration in pannus is confined to the corneal region lying between the anterior elastic lamina or Bowman's membrane and the corneal epithelium there is an intrinsic tendency to clear. In proportion, however, to the increased aggregation of cells, Bowman's membrane undergoes atrophic changes and finally is obliterated, thus permitting the process to extend more deeply. From a histological standpoint, pannus proves to be a layer of newly formed, soft, cellular tissue greatly simulating in appearance the infiltrated trachomatous conjunctiva. This tissue is more or less vascular and occurs in more or less typical layers imparting an uneven nodular aspect to the growth. Special terms have been assigned to the disease which are to a certain extent descriptive of pannus in the several types; thus we have pannus tenuis, which indicates a recent pannus exhibiting no great thickening; again, pannus vasculosus, signifies the vascular type, and pannus crassus or carnosus implies a very dense pannus; still further, we have pannus sarcinatosus, which is an unfortunate term, inasmuch as it gives an association with neoplasms; finally, we have pannus cicatricialis which is mostly composed of connective tissue containing few or no blood vessels.

The management of this class of cases the practitioner heretofore has been to cure the corneal inflammation from which the disease takes its origin and to be held that the pannus will sponta-

neously disappear; with this object in view various therapeutical measures have been resorted to, such as are usually exhibited in the treatment of trachoma; for example, nitrate of silver in solution or substance, sulphate of copper in solution or in the form of "blue stick" as it is called, and the various antiseptic measures have all found fitting application, and even the more radical measure of inoculation, either with the pus of an acute blepharorrhea as advised by Piringer and Jaeger, or the milder method of jequirity treatment first advocated by De Wecker. In conjunction with the foregoing ponderous array from the therapeutical armamentarium the surgical procedures of synechotomy, iridectomy and sclerotomy, and even an attempt at radical removal of the growth by scraping as advised by Grüening have all been utilized in these cases, and notwithstanding the great mass of literature that has accumulated in the course of time, we are still far from a unity of views with respect to the treatment of pannus. Within the last year I resorted to a mode of treatment which was particularly pleasing to me in its results and I herewith present an outline of the course adopted, not with any idea that it will wholly supplant the foregoing measures, but if it proves as efficient in the hands of others as in my own, that it may become an advantageous auxiliary in the management of such cases. I refer to the treatment of pannus, particularly that type characteristic of trachoma by the digestive ferments. The first case in which I employed a digestive ferment was in that of a man aged 45 who had suffered with trachoma and its ravages for a period of eight years. Papillary hypertrophy and trachomatous granules were still quite noticeable, together with very perceptible atrophy of the conjunctiva tarsi and a very pronounced pannused condition of both corneæ, which rendered it impossible for the patient to get about unattended. Entropion had also supervened. Viewing pannus as a new growth more or less vascular in type, I surmised that if I could but bring a medicament in contact with it that possessed powerful digestive properties I could favor its removal, and with this object in view I resorted to daily inspersions of powdered papoid with boric acid. Papoid is the new proteolytic agent derived from the carica papaya or papaw plant, and bids fair to become a most valuable addition to our materia medica. This agent exhibits the power of digesting all types of protein and albuminous substances, both in a coagulated and uncoagulated form, and its digestive properties are still further enhanced by the fact that it acts in acid, alkali and neutral media, though, as my experience demonstrates, more pronounced in alkali solution. So true did this medicament maintain its digestive powers that the remaining trachomatous granules gradually disappeared, and the pannus began to thin perceptibly; finally, after a course of constant medication with the before mentioned medicament, extending over a period of three months, such a marked change had transpired that the patient was able to get about unattended, and with the application of suitable glasses can read ordinary newspaper type at the distance of twelve inches and Snellen's D-18 at eighteen feet. When the process of clearing had reached its maximum degree the admirable operation designed by Dr. Hotz was instituted for the removal of the entropion, and thus the lids were placed more nearly in normal

opposition to the eyes, and the gentleman took his place in a very fair amount of vision in spite of many gloomy predictions to the contrary. The second case was that of a woman aged 30, who was suffering with chronic granulations and a papilled state of both cornea, though the pannus was not quite so dense as in the preceding case. Here the same favorable results ensued, the granulations gradually absorbing, the hypertrophic papillae disappearing and the pannus progressively diminishing in density until a fair amount of vision was restored to an individual who had abandoned all hope of ultimate recovery. The granulations melted away like a piece of ice in full sunlight and apparently had no tendency to reappear. A third case in which I applied the remedy is that of a woman aged 35, who had sustained a siege of trachoma affecting both eyes with consequent pannus of the vascular type, and in this case as in the preceding, a diminution of all the inflammatory symptoms ensued together with pronounced thinning of the pannus, and perceptible clearing of the cornea with great improvement of vision, and I am convinced by the foregoing cases that we have in the digestive ferments, particularly papoid, a very efficient and safe digestant applicable in these cases.

The argument will no doubt be advanced that it is not possible to digest living animal membrane to a degree sufficient to warrant the application of the remedy in such cases, but in opposition thereto, I hold that the new growth is necessarily of low vitality, depending as it does for its nutritive pabulum upon the conjunctival and embryonic vessels peculiar to itself, and is largely composed of lymphoid structures which have appeared to be particularly susceptible to the digestive influence of the ferment. In order to demonstrate its powerful digestive qualities I immersed a densely leucomatous eye which had been blinded by smallpox and recently enucleated and present it herewith for your inspection. You will notice that it is almost completely digested. It is now one week since the eye was thus treated, the strength of the solution being 30 grains to the ounce, and indeed it had reached its present state of digestion on the second day of its immersion which indicates that papoid exhibits powerful digestive qualities when brought in contact with animal membrane, and certainly if it is capable of virtually digesting the cicatrized envelope of an eye, which as we know even in a normal condition is quite resistant to the action of chemical agents generally, its effect in this instance is strikingly suggestive, and leads to the conclusion that its digestive properties have not been over estimated. In an article entitled, "Some Observations on the Clinical Uses of Papoid," by Dr. Arch Dixon of Kentucky, he states that "he has used papoid with marked benefit in diphtheria, membranous croup and indolent ulcers, and as a solvent for dead bone." My own experience while still limited, leads me to confirm his conclusions when he says, "that papoid under papoid conditions produces greater results than pepsin under pepsin conditions." I have made application of pepsin, both in solution and in powdered form in cases of granular conjunctivitis associated with pannus, and have not reached the satisfactory results that I was able to obtain with papoid.

Dr. TAYLOR—In what proportion is papoid and borie acid used, and how often is the application made?

Dr. LANSOE—Papoid is applied to the eye in the form of ment of patients, the quantity being about 20 grains to the ounce, that often, after a few days, only a very small use equal parts of papoid and borie acid.

Dr. BERRY—In what strength does papoid dissolve, and how do you apply it to the eye?

Dr. LANSOE—I take equal parts of papoid and borie acid, after mixing them thoroughly I dust them into the eye by means of a camel's hair brush, only a slight reaction following.

SELECTIONS.

Pathological Models at the World's Fair.

In order to draw attention to some of the exhibits from the Pathological Institute of Berlin University, now on exhibition at the World's Fair, we reprint herewith Dr. BERLINER's account of these from an article originally published in the *Deutsche Med. Wochenschrift*:

"Plastic Reproductions of Preparations from Pathological Anatomy," by Dr. PAUL BERLINER, Berlin, Germany. In any demonstrative science, clinical instruction is of the greatest importance, therefore every teacher of medicine, whenever possible, endeavors in his lectures to help his hearers to an easy comprehension of his subjects, either by exhibition of a patient, of pathological preparations and instruments, or corresponding illustrations of the same. For this reason, also, medical literature contains abundant illustrations, for the production of which all forms of graphical methods are brought into use. However, notwithstanding the perfection of photographic, chromographical and similar illustrations, medical science often presents to the student cases in which the mere physical aspect, or gross anatomy, is insufficient, and a plastic representation is necessary for a clear understanding thereof. This is especially true when applying to dermatology, embryology, or normal and pathological anatomy. If, therefore, from the plastic reproduction or representation the model is perfected by careful coloring copied from the original, it should certainly be the most complete way of permanently presenting those natural objects which are themselves rapidly perishable, and retaining the peculiarities of their changeable, or temporary appearances and conditions. The combination of "polychromy" with plastic art makes it possible to produce objects wonderfully similar to the fresh, natural preparation.

The idea of perfecting plastic preparations is not a new one. At first it was confined to only normal anatomy and later pathological anatomy. Preparations were formed out of various materials chiefly wax, and brought together in collections.

In literature, only isolated notices are occasionally found of such collections, which I have gathered together as far as possible without attempting completeness.

Hyrthl, in the preface to his *Anatomy of the Human Body*, states that Emperor Joseph II. had presented to the school of military surgeons in Vienna a new extension of the most world-renowned collection of anatomical wax preparations, equaled only by a similar one in Florence, where the collections were made under Fontana's direction by the Italian artist Gaetano Zumbo and the Spaniard Novesio.

The anatomical museum in Vienna contains a few wax models made by Dr. Dom. Bastren, a practicing physician of that city in the latter part of this century. At the present time these anatomical wax preparations are made principally

pally in Paris and Lille, from whence they are exported all over the continent. Most of that class of models exhibited in Germany, particularly those of a pathological character, are of French origin. Most famous in Paris, is the Muséum Baretta in the Hospital St. Louis, as is also the syphilographic collection of "Jumelin."

Among other manufacturers should be mentioned "Tramond" of the medical faculty of Paris University. He has published a voluminous catalogue of his preparations.

The department of Pathological Anatomy of the Berlin Charité, possesses a collection of models which were made by Dr. Felix Thilbert of the Paris University.

Prof. Schüller, in a recently published account of his travels, states that most of the North American Universities also make use of wax models in their didactic and clinical lectures, and Prof. Schüller informs me these have also been imported from Paris.

In Germany, models of normal anatomy are manufactured in Munich and Dresden, and a Dr. A. Ziegler of Freiberg, furnishes preparations for the study of embryology.

Herr Lassue of Berlin, has directed his attention to the plastic reproduction of skin diseases, and has laid the foundation for a large collection of dermatological wax models which are reproduced from material furnished by his clinics.

As for myself, I at first made plastic preparations from only the skin clinics of the Breslau University, but soon made use of them in other departments of pathology, especially from diseases peculiar to the viscera. I believe I can claim the right of priority in the introduction of the last named preparations. My intention is to introduce this method of reproduction more generally by such preparations, and I believe it is deserving of more attention from the medical profession than has heretofore been accorded it. The practical advantages of these preparations from whatever medical specialty they be taken, is that while in possession of these artificial reproductions one has always at hand an exact imitation as to size and coloring of the original, and can make use of them while teaching, either for demonstration or comparison with other preparations. Herein lies also the advantage of this method of illustration over the use of the originals, which being preserved in fluids are subject to constant change in form and coloring. Also the rapidly changing appearances on the living subject afford only a more or less unsatisfactory objective picture of the disease in question, and therefore with the model we possess a permanent reproduction or appearance of the different morbid conditions and are not obliged to depend on memory, or the individual conception of a single observer.

There are important manifestations of certain diseases which the medical man during his student years finds no opportunity to become familiar with, perhaps because of the lack of clinical material or because during his course of clinical study these diseases were not prevalent at the time, but nevertheless diseases which every physician must be familiar with; as for instance the exanthema of typhus, etc. In such cases a model perfectly true to nature may well serve for instruction and demonstration, in default of clinical material. Among the various departments of medicine in which these plastic preparations are serviceable besides dermatology, is normal and pathological anatomy, and all the different newer methods of surgical operation, which can be well demonstrated on the plastic models. Also certain conditions and appearances which are continually observed on the patient, resulting from various causes, can be permanently fixed and reproduced by this plastic method. I have thus illustrated by the models in the skin clinics of the University of Breslau, the various manifestations of lupus affections which

took place under the tuberculin treatment of Koch. This should clearly demonstrate the value of these plastic preparations, for now that the above treatment has been abandoned, they offer for present and future consideration a vivid conception of those therapeutic measures which caused so much excitement in the medical world. On the other hand, they will serve as objects for comparison and demonstration in case of renewal, improvement or adoption of another method of treatment.

During epidemics, pathological changes in single organs, which differ according to the virulence of the poison, can be obtained and preserved in the same manner.

These preparations are made by first taking a plaster cast of the subject to be reproduced. This mold is then filled with wax made liquid in a water bath, and a positive is thus produced. The model is then carefully painted with oil colors, true to nature. Later, various varnishes are applied to give to it the moist appearance of the fresh or living tissue, and upon the correct imitation of which it depends.

The most difficult part of the work is the correct coloring, and this is especially true in pathological more than in dermatological preparations. In skin diseases the lesions are generally more scattered and better defined, while in pathological subjects the whole surface must be correctly reproduced in its natural coloring.

Among the preparations exhibited by Dr. Berliner are mentioned the following:

1. Uterum, showing a placental changes of the mucous membrane. Five cm. from the anus a scar contraction. On the anus itself, a large hemoroidal tumor. Further, a rectal ulcer after catenization with the Papanicolaou, showing where healing had commenced. Slight edema seen in the lining and pigmentation of the mucous membrane. The submucosa and muscular coats are plainly shown in the drawing.
2. Kidney of a newborn infant, with uric acid infarcts (see concentric).
3. Aorta—end arteritis—4 forms—(with atheromatous degeneration). Chronic enlargement (or dilatation) of the aorta.
4. Stomach, with ecchymosis in the pylorus, showing scattered spots or areas of hyperemia on the mucous membrane.
5. Stomach with secondary carcinoma of mucous membrane (metastatic).
6. Liver—Chronic interstitial hepatitis with jaundice (cirrhosis).
7. Lungs, with emphysema, collapsed after opening chest cavity. Bronchopneumonia (or hepatization) in lower lobes.
8. Lungs, showing active hyperemia.
9. Section of lung with multiple cheesy deposits (pneumonia). Bronchial and peribronchial inflammation.
10. Section of lung, showing recent pleurisy. Excessive thickening of the pleura.
11. Larynx, with polypus on under half of right vocal cord.
12. Larynx, with epiglottic ulceration of the epiglottis.
13. Larynx, with tubercular changes.
14. Pericardium, with simple infection.
15. Bladder, with 1 right and 1 left ureter.
- NOTE.—Nos. 1 and 2 are in the possession of Herr G. Lewin, director of the skin clinics of the Royal Charité.
- Nos. 11, 12 and 13 are in the possession of Herr Prof. Dr. Frankel, director of the clinic for throat diseases of Royal Charité Hospital.

Memorandum of a Case of Hydatids of the Kidney, with some Remarks.—By JOHN B. HAMILTON, M. D., LL. D., Chicago, Ill. Professor of principles of surgery and clinical surgery in Rush Medical College.

In January, of this year, a young Dane came into my clinic as a patient, complaining of occasional attacks of renal colic. On inquiry he stated that he had noticed after these attacks, certain white substances which his imperfect knowledge of English prevented him from describing. I directed him to return when he was next attacked by colic, and enter the hospital.

About the first of February he returned and I was enabled to see the substances passed with the urine, and I found them to be capsules of echinococci. Careful examination was then made by abdominal palpation and the kidney was found enlarged to a considerable degree. The patient's general condition did not seem to be affected, and his sole annoying symptom was the recurrent attacks of renal colic.

Examination of the urinary deposit under the microscope showed the hooklets of the echinococci in limited numbers, and on February 4, 1893, at the Rush Medical College

clinic, I cut down upon the kidney by lumbar incision, made parallel with last rib. The kidney was exposed and the perinephritic space packed with iodoform gauze, and an incision made directly through the kidney toward the pelvis. The fluid contents of the cyst escaped through the wound, and daughter cysts round, white and shining, rolled out of the incision in great numbers. Irrigation was then practiced, and the parent cyst having been entirely emptied of its contents was flushed with iodine water, and the wound was packed to the bottom with iodoform gauze. The patient was comfortable after the operation, progressed toward a rapid convalescence and was well in four weeks.

Although hydatids of the liver are comparatively common, those of the kidney are infrequent, and it is on account of this circumstance that I venture to present this brief case report. There is now little dispute concerning the treatment of echinococci of the kidney, when a diagnosis is made; free incision is obviously the only correct procedure, but there is yet much to learn concerning the etiology and mechanism. The dog, wolf and kangaroo have the general reputation of being the original host of these echinococci. Their habitat is in the small intestine of those animals. There is circumstantial evidence to corroborate this reputation in the fact that it is precisely in those countries where dogs and the animals named are more common that the echinococcal disease is most prevalent. Iceland and Australia have the prominence in frequency. Cobbold states that in Iceland one-sixth of the mortality is caused by hydatid disease.

Thomas published statistics of 7,156 cases of echinococcal disease observed in the hospitals of Australia. He found 59.06 per cent. located on the liver; 16.44 per cent. located in the lungs; 2.55 per cent. located in the epiploon and peritoneum, and 1.80 per cent. located in the muscles. Thomas, in 307 cases, found only two located in the kidney, but in Davaine it is stated that of 500 cases of echinococcal disease, thirty had their seat in the kidney. One fact is noted in regard to hydatids of the kidney which seems to have no reasonable explanation; that is the greater frequency of the disease in the left than in the right kidney. I am not prepared to offer even an hypothesis as to this fact which has been noted by all systematic writers on the subject.

The allegation that the disease is more frequent in women than men might have an explanation in their greater fondness for pets, and the habit of kissing them.

The statistics of ages of persons known to be affected by hydatid disease, vary from six years to sixty-five years, but the average is between twenty and thirty years.

The practical lesson from these cases is that the disease is preventable, and appropriate hygienic measures should be adopted by those engaged in the slaughter of animals. These measures consist in the care to be taken that no cystic tumors shall be allowed to go with the other offal, but be burned in a crematory, and by persons handling dogs that they do not kiss them, or allow the dog to lick the face. My patient admitted that he had eaten raw meat, and kept several dogs, from either of which sources he might have obtained the ova of the cestoid.—*Kansas City Medical Leader*.

Calomel as a Topical Application to Hemorrhoids.—Dr. J. B. James has written in favor of the above treatment, in *British Medical Journal*. He states that he has for several years made use of calomel as a topical application to piles. His success has been quite marked, especially in cases where inflammation has been produced in the abnormal tissues, characterized by mucous discharge and hemorrhage. Under this simple treatment the annoying symptoms were generally soon relieved, and the patient absolved from the necessity of undergoing a perturbing course of treatment.

This method leads to the free introduction of the parts, and cleanliness is of itself a guarantee of a successful cure. The calomel is a cleanly kind of application, and commends itself to the patient for frequent and regular application. It is readily applied and does not stain the clothing.

SOCIETY NEWS.

American Dermatological Association.

Abstract of the Proceedings of the Society for the Study of Dermatology, held in Montreal, Quebec, Sept. 24th, 25th, 26th, 27th, 28th, 29th, 30th, and Oct. 1st, 1893.

Dr. E. B. Brissson, of New York, followed with a paper entitled:

THE TREATMENT OF PRURITUS.

The author said in the management of *pruritus*, generally, as of any other disease, the first consideration should be directed to what caused the trouble. The adoption of measures tending to remove any accidental conditions or influences through which pruritus might be occasioned is important. Such causes include, besides various local sources of irritation, certain remote or general diseases and furnish the *calentamiento* of its limits more limited sense. This, however, states the scope of the problem only partially. What is of more importance is to establish principles of treatment fitted to those more special and more essential causes that constitute the necessary conditions of the disease and whence we derive the *dermatitis*. Those causes are traced under etiology, and it is they which must afford the only intelligent basis for the therapeutics of pruritus.

The chief underlying condition in pruritus is hyperesthesia, whether in its common significance of an excessive irritability of the sensory nerves, or in the sense of an excess or engorgement of sensation. The prime indications, then, are to allay irritability and to divert or annul the excess of nervous excitement. Measures to remove local excitants include, first of all, such as directly tend to prevent scratching. To admonish the patient to refrain from this is usually of little avail. Restraint may be possible during waking hours, but at night, when the trouble is always at its worst, and especially during the state of somnolence midway between sleeping and waking, no power can prevent it. It can only be avoided by first mitigating the lesion through the aid of anti-pruritics. Sedatives when used internally are apt to be disappointing. The degree of general sedation that is required to affect the nerves of the skin in so intense a disturbance as pruritus often is, affords a sufficient reason why this method of treatment is usually objectionable. Further than this, the depressing and atonic after effect on the nervous system tends to exaggerate the general hyperesthesia which is already essentially an atonic condition, and thereby increases the tendency to itching. Especially objectionable are most of the narcotics. The bromides, on the other hand, are often indispensable and may be required in liberal doses. It is important to avoid the enervating effects of loss of sleep, and for this purpose sulphonal or some other hypnotic is occasionally needed. In connection with this, two internal remedies which have been recommended by Bulkley are worthy of mention, and they are cannabis indica and gels-minum. The former is known to be a cutaneous anesthetic as well as an analgesic, and by virtue of the former quality should be useful in pruritus.

Carbolic acid is the most reliable and most generally useful anti-pruritic which dermatologists possess. It was well named by Unna "the opium of the skin."

The following "anti-pruritic oil" has been much employed by the author for years, both in local and so-called universal forms of the disease, with no more untoward results than now and then a trifling dermatitis, when through oversight the patient has been allowed to make the applications too frequently, or has continued them too long. The formula is:

R. Carbolic acid, 5i-ii.

Liquor potass., 3i.

Oil, lini, 5i.

Sig.: Shake before using.

To correct the disagreeable odor of the linseed oil a drop or two of benzoin may be added. Salicylic acid and salol though less energetic in their effects, act similarly to the carbolic acid. Thymol is also an admirable anti-pruritic.

but on account of its irritating effect can not be used when the skin is sensitive.

The author then dwelt on sensory stimulants, substitutive irritants, alternatives of cutaneous nutrition, and motor depressants. In pruritis hiemalis an all important measure of treatment is protection against cold. The sole cause of winter pruritis, aside from a special predisposing hyperaesthesia, is lowered temperature.

DR. JOSEPH ZEISLER of Chicago, Illinois, read a paper entitled

ANGIOKERATOMA.

and reported the following case. The patient was a German, and 53 years of age, butcher by occupation. Had never had any severe illness, but had malaria once. Present illness began somewhat gradually about four years ago with red spots and verrucae on the skin of different parts of the body. He was under medical treatment and says he improved for a time. He states that some of the red spots gradually disappeared at times, but returned and new ones arose in different localities. During all this period his general health had not suffered in the least. No anorexia, headache, nor any other complaint. There is no pain or itching in the skin lesions. Patches of vitiligo of large size are found on the front and sides of the abdomen and on the right side of the thorax. Some small patches in right axilla. Faint patches on right side of chest posteriorly and on the neck. Large patches on the penis and scrotum and small ones on the inner surface of the thighs. There are some old marks of tinea favus on the scalp. Navus-like spots and small tumors are scattered over the body as follows: On posterior surface of right ear are two small warts, red in color and vascular; one on posterior aspect of left ear. On the ulnar surfaces of both forearms, beginning over the olecranon, are found red navus-like patches of irregular contour and smaller isolated ones in the form of small pedunculated tumors. The patches vary in size from three or four inches in circumference to the size of a dime. They are red in color, vascular and slightly raised above surface of surrounding skin. On the right forearm are numerous small tumors varying in size from minute spots to some the size of a hazel-nut. The larger ones are all pedunculated, firm and vascular. On the left forearm they are fewer in number. Considerable edema in the right hand and fingers. Only one or two small warts on the extensor surface. On palmar surface there are some on every finger except the index, and none on the wrist and ball of the thumb. One was removed and found to consist of an outer layer of thickened epidermis surrounding a very vascular center. Microscopical examination was made by Dr. Zeisler. Some of these tumors sprang out from beneath the finger-nails. On the left hand the verrucae were not so numerous and inclined more to the small vascular variety with two exceptions. Large irregular red patches were also found over each patella, and a few smaller ones irregularly scattered over anterior aspect of the legs and thighs; also a few smaller ones over the posterior aspect of thighs and one over the back of each ankle. Two small pedunculated warts were also found on the back of right leg, another with some of the red patches on the nates near the gluteal fold. No patches or tumors were found on abdomen, thorax or upper part of arms.

The author reported this unusual and interesting case to show that the clinical picture of the disease is evidently not yet quite complete, and hoped that new examples of the disease would arise which would throw more light on the pathology and etiology of the affection.

DR. J. A. FORDYCE of New York, read a paper entitled

A CONTRIBUTION TO THE PATHOLOGY OF ACNE VARIOLIFORMIS (CHEREA).

Dr. Fordyce called attention to the case described by Dr. Brinson and himself in 1891 under the title of "Acne Varioliformis of the Extremities," which was at that time shown to originate in or about the coil glands. This was identical

with the cases since reported by Politzer, Dubreuilh and others under the name of hydradenitis, and should go on record as a example of that affection. While clinically it presented many points of similarity to acne varioliformis

its histological anatomy was quite distinct.

Dr. Fordyce had examined microscopically a number of sections of papulo-pustules from two typical cases of the disease and was able to trace its beginning to an infection of about the middle and upper portions of the coiled ducts and their sebaceous glands, while the coils themselves were shown to be outside the inflammatory area.

Enormous numbers of staphylococci were found in sections from one of the cases examined which readily stained with Kühne's carbolio-methylene blue solution. These organisms were especially numerous about the middle and deeper portions of the hair follicles and contained within the external and internal root-sheath, in the connective tissue about the coil glands and in the subcutaneous connective tissue. In considering their number, distribution and presence in the diseased area before the epidermis was involved, the writer was disposed to consider them a direct influence in producing the lesions. In a secondary infection they would scarcely be found at so early a period in the evolution of the papule.

As a result of his investigations, Dr. Fordyce concluded that acne varioliformis (Hebra) was an inflammation of the pilo-sebaceous system, of microbial origin, leading to destruction of these organs, and that Bazin was correct in naming the disease acne pilaris.

The members of the Association, at the close of Dr. Fordyce's paper, participated in a general discussion on pityriasis rosea, and pemphigus.

The following officers were elected: President, Dr. Robert B. Morison of Baltimore, Md.; Vice-president, Dr. George T. Jackson of New York; Secretary and Treasurer, Dr. Charles W. Allen of New York; Member-at-Large of the Council, Dr. J. A. Fordyce of New York.

On motion, the Association adjourned to meet in Washington, D. C., in May, 1894.

The Missouri Valley Medical Society, at its meeting held in Council Bluffs, Iowa, Sept. 22, elected the following officers:

President, Dr. A. F. Jonas of Omaha; first vice president, Dr. A. L. Wright, of Carroll, Ia.; second vice president, Dr. Daniel Morton of St. Joseph, Mo.; treasurer, Dr. T. B. Lacy of Council Bluffs; secretary, Dr. F. S. Thomas of Council Bluffs. The next meeting place will be at Omaha.

The Cedar Valley Medical Society.—The annual meeting of the Cedar Valley Medical Society will be held in Dubuque, Iowa, Tuesday, October 10. Papers will be read by the following: Drs. J. W. Jaggard, Chicago, Ill.; J. S. Lewis, Dubuque; G. F. McDowell, Clear Lake; W. Woodbridge, Central City; E. C. Dudley, Chicago; A. R. Brackett, Nashua; E. Hornbrook, Cherokee; C. L. Whitmire, Waverly; H. C. Jungblut, Sumner.

The meeting will be followed by a luncheon. Dr. I. S. Bigelow is president of the Society and Dr. W. B. Small, of Waterloo, is secretary.

The Southern Surgical and Gynecological Association will meet in New Orleans on the 14th, 15th and 16th days of November. The medical profession are cordially invited to attend. Dr. Bedford Brown of Virginia is president, and Dr. W. E. B. Davis of Birmingham, Ala., secretary.

ASSOCIATION NEWS.

We clip the following from our valued and always welcome contemporary, the *Occidental Medical Times*:

OREGON AND THE ASSOCIATION.—Dr. Plummer informs us that a member of the Association from Oregon writes to say that he wishes to present the different sections with a souvenir of their visit to the Pacific coast that shall be typical of the State of Oregon. This incident indicates the interest in the Association that is being rapidly developed, and augurs well for the success of the meeting.

THE SAN FRANCISCO COUNTY MEDICAL SOCIETY.—At the last meeting of the San Francisco County Medical Society, Dr. C. G. Kenyon, the President of the State Society, brought up the subject of the meeting of the Association in '94. After some discussion the Society appointed a committee to cooperate with the Committee of Arrangements of the Association.

COMING TO CALIFORNIA.—Dr. H. Bert Ellis of Los Angeles the Assistant Secretary of the Association, informs us that he is already constantly in the receipt of letters from members of the Association who are preparing to attend the meeting. He says that several of his correspondents want to come on in advance and stay all winter—we presume in Los Angeles.

THE Journal of the American Medical Association PUBLISHED WEEKLY.

SUBSCRIPTION LIFE, FIFTY DOLLARS
PER ANNUM, IN ADVANCE
SINGLE COPIES, FIVE CENTS

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 N. WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Address to the
Treasurer, RICHARD J. DUNCANSON, M. D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any State or National Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duncanson, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 7, 1893.

THE PLACE OF ERGOT IN OBSTETRIC PRACTICE.

There is probably no therapeutic application of a drug so constantly carried out as the administration of ergot in obstetrics, and yet this being the case there is no doubt that in many instances it is wrongly administered because it is not needed, because it will do harm and finally because it is given at such a time that uterine contraction is voluntarily or artificially produced by other means before the ergot is absorbed, and so it exerts its action long after the object of the physician has been accomplished. On the other hand, as pointed out by BOHX in the JOURNAL of Sept. 23, 1893, there are very good reasons for this routine practice. It is positively certain that postpartum hemorrhage can almost always be avoided, even in feeble patients by its use, and in cases where there is no trained nurse in attendance and the doctor can not remain for some hours near his patient it must be given, without exception, if the safety of the case is to be assured and the physician is to have his mind at rest. In the discussion of the paper it will be remembered that DUFF expressed doubts as to the harmlessness of the routine use of ergot, as he had already done in a paper in the *Therapeutic Gazette*, in which he asserted that ergot was apt, by producing contractions of the uterine muscle at the cervix, to lock up debris which might when imprisoned produce septic trouble. Practically, however, we do not believe that such an accident is liable to occur. On the other hand, it is undoubtedly a fact that the contraction of the uterine walls produced by ergot, drives out of its cavity blood and other materials, and finally it is certain that these substances are more septic in themselves and are not readily changed to a septic state, unless the obstetrician has passed his hand or instruments into the cavity of the uterus and so infected them.

The rule with ergot is, if the case is one in which labor is hard, to give it. As with the use of any other drug, the judgment of the physician is the only guide. The law, Ergot must not be used too early, too late, and neither be increased, neither must it be used too late. As it takes almost an hour for the dose to be absorbed, when given by the mouth, the influence of the drug on the uterus can not be felt for that period, and there is therefore no danger in giving the drug as soon as the physician is certain that labor will be over, at least so far as the truth of the head is concerned, in half to one hour. We therefore believe that ergot is to be used in almost every case where the physician can not be at hand the instant hemorrhage or uterine relaxation is threatened, and that the practice so generally followed is productive of an amount of good which far outweighs the few instances in which it may not produce the best of results.

PROPHYLAXIS OF CHOLERA—RAPID DISINFECTION.

At the session of the Academy of Medicine of Paris on the 19th of September, M. LE FORT presiding, M. BROUARDEL invited attention to the fact that at the preceding session M. BABES had read a memorial showing that in 1890 Roumania, contrary to other countries of Europe, had escaped the cholera epidemic, thanks to quarantines which, following the ancient system had been applied in all their rigor. This rigor had been such that they had not hesitated to shoot two persons who had tried to force the land quarantine. On the contrary, in 1893 when the quarantine had not been applied, Roumania had been invaded by cholera in the same measure as the neighboring countries. From this M. BABES has leaped to the conclusion that the Dresden conference had in suppressing land quarantines adopted a fatal measure. "It is not doubtful," said M. BROUARDEL, "that the suppression of quarantines, pure and simple, without replacing them by similar measures, more simple than the former, in effect exposes Europe to the cholera infection, but such is not the result of following the conference of Dresden."

In the presence of the great inconvenience of the quarantines, which permitted disinfection, vaccination and, above all by time, it was asked if it were not possible to obtain the same result by means of rapid disinfection. It is easy to see that the existing measure adopted by the powers represented at Dresden, are precisely those which were the objects of the conference as indicated in the question proposed. These measures were pointed out to be such as disinfection by sterilizers, isolation of the sick, traveling card to be carried by well persons, etc. These statements of M. BROUARDEL are reassuring.

for they show that inspection is not proposed to be abandoned by the French, but only simplified and hastened.

EDUCATIONAL MODELS.

We print elsewhere a report by DR. BERLINER on the method of preparation of models which will be read with interest for, although originally printed a twelvemonth ago, the bringing of some of them to America as part of the German educational exhibit at the World's Fair, makes the description fresh and entertaining.

Teaching is but dry work without models or demonstrations, and one might as well undertake to teach practical anatomy by book, as pathology without diagrams and illustrations; as well also might the student learn the art of opera dancing by nightly observation of the ballet, as to learn the delicate handling of the scalpel without long practice on the cadaver. Our students require more practical training than ever, for it is not less true now than in the days of KING AGESILAUS, whose answer, when asked what a boy should learn, was, "that which they ought to do when they become men." Medical colleges have been rather slow in the adoption of the educational methods in use in other branches of learning, but they now seem pressing forward in the right direction and, as in agriculture, certain preparation of the soil must precede the planting, so the object lessons of the schoolroom prepare the mind of the student for the technical models of the medical school, and for the severer test questions of daily life, when school days are long past.

THE SANITARY MODE OF OATH ADMINISTRATION IN THE COURTS.

The *London Lancet* and the *Sanitary Record* have been foremost in counseling abandonment of the "kissing of the book" by witnesses in the courts of justice. It is practically an act of injustice, oftentimes, this long standing custom of bringing together, through the medium of the book, face to face and mouth to mouth, the cleanly and healthy, the uncleanly and infected. A physician of London has recently been the subject of considerable public comment for declining, on sanitary grounds, to take the book oath. The following is a condensed account of the recent occurrence taken from the *Pall Mall Gazette*:

"The kissing of the book" is likely before long to become one of the lost arts. Another objector to the practice has turned up in the West London Police Court in the person of Dr. Morris Wallace, called to give evidence in a case where one woman was charged with stabbing another in the eye with a fork. The doctor said he had no religious scruples, but he considered that there was a risk to health involved in putting to his lips a book which had already been kissed by other people. The magistrate suggested as a compromise kissing the inside of the volume. But here, too, the doctor objected "on sanitary grounds," and he was finally sworn by holding up the right hand."

This may be the beginning of a "reform movement;" and if so, it is only natural to see a medical man stepping to the front. Not a few of our medical acquaintance habitually adopt the oath by affirmation, instead of the traditional method, in regard to which, it is no slander to remark that it is more honored in the breach than in the observance.

MEDICAL EDUCATION.

The Illinois State Board of Health at its last meeting, decided to resume the publication of the reports on medical education. For the last two years, owing to various causes, none have been printed. DR. J. COLLINS WARREN, President of the Section of Pedagogy of the Pan-American Medical Congress, in his address, after reviewing the subject in this country, says:

"The reports on medical education by the Illinois Board, I do not hesitate to say have exerted a more powerful influence on the movement in education than any other publication which our medical literature has produced."

This is undoubtedly true. These reports were object lessons to the profession and to the schools, and presented truthfully the status of the colleges. DR. F. W. REILLY is now engaged in preparing the forthcoming report. He is eminently qualified for the task, having assisted in the preparation of nearly all the reports that were issued by the Board.

CHICKEN POX OR SMALLPOX.

The death of DR. THOMAS RICHARDS at North Brothers' Island of smallpox is very sad. It may be said to be the result of mistaken diagnosis, and carelessness upon his part in not being properly protected by vaccination. He contracted the disease from a case of supposed chicken pox that was brought before the Vanderbilt clinique, which afterward proved to be smallpox.

This is not the first time that a mishap of this character has occurred. It is simply impossible always in the early stages to differentiate these diseases. The man who says he can always diagnose a mild case of smallpox or varioloid has only encountered typical cases, or has had but a limited experience. Experience has taught that the only safe way is to treat such cases as suspects, and wait for development. Bringing uncertain cases of this character before classes during a clinique is unsafe, so long as all unexposed persons are unprotected by vaccination.

French Sanitary Commissioner at Constantinople.—Pursuant to a request from the Ottoman Government M. Charte-messe has been sent by the French Government to preside at the inauguration of the measures of combating the cholera which has been active in that city.—*Bulletin Medical*, Sept. 20.

RUPTURE OF SMALL INTESTINE—LAPAROTOMY—ONE DEATH, TWO RECOVERIES.

BY H. C. DALTON, M.D.

ST. LOUIS.

Professor Abdominal and Clinical Surgery, Marion Sims College of Medicine; late Superintendent St. Louis City Hospital.

Rupture of the intestines is so rare that I am sure the report of the following cases will prove of sufficient interest to the Association to justify me in taking up a few moments of your time. The cases particularly emphasize the urgent need of early interference in such injuries, if we would save our patients from rapid peritonitis and death.

CASE I.—RUPTURE OF JEJUNUM AND MESENTERY—LAPAROTOMY—DEATH.

J. W., *et. 22*; laborer; entered the City Hospital in October, 1893. Twenty hours before admission, while stealing a ride on a freight train in Illinois, he fell from the top of the car striking his belly against the handrail in the descent. He was brought to the hospital at 1 p. m. next day. His temperature at that time was 103 F. Pulse 120 F. Percussion gave dullness in the dorsal gutters, and resonance anteriorly. He was at once prepared for laparotomy. Dr. D. H. Mudd, who was holding a clinic at the time, kindly assisted me in the operation. After thorough antiseptic precautions a median incision eight inches long, was made. The cavity was found full of clotted and fluid blood. The necessary handling of the intestine caused fresh bleeding which was at first thought to come from the liver, but a careful search revealed a complete transverse laceration of the jejunum at its spinal attachment, the end of the gut being separated to the extent of an inch or more. The mucous membrane was greatly everted. The tear extended an inch into the mesentery and owing to the depth of the rupture it was manipulated with great difficulty. The mesentery was closed on both sides with interrupted iron dyed silk sutures. An ordinary canalic needle two inches in length was used. The upper end of the gut was inserted into the lower and the serous surfaces brought together by the interrupted Lembert suture, a large number being required. The blood was washed from the cavity and the surgical wound closed. Drainage was not used. The patient never rallied from the shock, and died a few hours after the operation. I can but believe that this patient would have recovered had he been brought to the hospital the day before. The intestine was quite red though not adherent, peritonitis not having advanced sufficiently far to produce that effect.

CASE II.—RUPTURE OF JEJUNUM—LAPAROTOMY—RECOVERY.

John I., *et. 17*; hostler; entered the City Hospital at 9 a. m. Feb. 8, 1892, a half hour after being thrown from a horse. The horse also fell and rolled over on the boy, boring the horn of the saddle into his belly. A scalp wound four inches in length was found three inches above the left ear, from which a considerable quantity of blood had escaped, sufficient to thoroughly saturate the patient's clothes. Although the patient admitted shortly after admission that he was suffering considerable pain in the abdomen, he afterwards denied it, referring all the pain to the scalp wound. I learned later that a patient in an adjoining bed had warned him that if he admitted having pain in the belly the doctors would "cut him open." Five or six hours after admission he reluctantly gave me the above history. Careful inspection of the abdominal surface failed to show the least bruise or abrasion, but deep pressure gave pain in the umbilical region, and percussion gave dullness over the left side of the belly. There had been considerable vomiting. His pulse was now 105 F., temperature 101.5 F.

The scalp wound had been cleaned and closed shortly after his entrance into the hospital. After thorough antiseptic precautions a medial incision five inches long was made. The small intestine was found collapsed. This was followed to the upper portion of the jejunum where a transverse rupture an inch and a quarter in length was found. Considerable blood and fecal matter was found in the left dorsal gutter. This was washed out with warm physiological salt solution. The wound in the gut was closed by interrupted iron dyed silk Lembert suture. A glass drainage tube, surrounded by iodoform gauze, was placed in the pelvic cavity and the belly closed. The tube was cleaned every hour for twelve hours. Then at increased intervals for four hours, after which it was removed.

The patient rallied nicely. His temperature for four days varied between 100 F. and 101 F., after which recovery was rapid.

At the time of the removal of the tube, an accident occurred which had happened in several of my previous cases, i. e., portions of the omentum had become strongly attached to the openings in the tube. I found it impossible to detach the omentum until I had excised the invaginated portion. The fistulous track left by the tube was filled with iodoform gauze, and a snug dressing applied. The patient was discharged well March 20, twelve days after admission.

CASE III.—RUPTURE OF ILEUM—LAPAROTOMY—RECOVERY.

Peter M., *et. 20*, was admitted into the hospital at 4 p. m., Nov. 20, 1891. Three hours prior to admission, while feeding a circular saw a piece of wood became detached, and with great force was thrown against his abdomen. In a few minutes he grew faint and was compelled to lie down. Vomiting soon developed, and pain became intense. When admitted to the hospital he was in great pain paroxysmal in character. Shortly after this he again vomited. His pulse was 116 F. and weak; hands and feet cold. The face wore an anxious expression. The respiration was hurried and superficial. Examination of the belly showed a very slight abrasion four inches in length, extending from right anterior superior spinous process to umbilicus. Percussion over this region gave a tympanic note. There was also some swelling at this site, as well as great tenderness and pain on pressure. The urine was drawn and found normal, indicating an intact bladder. His rectal temperature was 105 F.

At 7:30 p. m., three and one-half hours after admission, I opened the belly. Prior to doing this, however, I had in the presence of Drs. French and L. I. Mathews (who were visiting me at the time), made the diagnosis of ruptured intestine. An incision four inches long was made in the right linea semilunaris which bisected the abraded portion about its middle. Upon drawing out the ileum a transverse rupture about an inch long was found. This was closed by five or six interrupted Lembert iron dyed sutures. The omentum was also stitched to the wound. A small quantity of fecal matter and a large quantity of peritoneal secretion was sponged from the cavity, after which it was closed without drainage, save a small piece of gauze which was left in the lower angle of the wound. This was removed on the second day with great difficulty owing to the firm adhesion of the gauze. Peritonitis had not developed.

There was some contusion and hematoma in the adjoining mesentery. The cavity was not irrigated, but the intestinal coils, while out of the belly, were washed with the salt solution. As in the preceding case, the small intestine below the rupture was collapsed. (This condition is almost always present in such cases as well as in intestinal obstruction.)

(An interesting feature of this case was that a Meckel's diverticulum was found a short distance below the rupture. It was an inch in length and about the same in width.) The wound healed by first intention, and the patient's recovery was rapid and uninterrupted. Flatus and feces passed for the first time on the second day.

I attribute the success in the last two cases to the early operation. I believe, in the hands of a careful surgeon, almost all such cases can be saved. Of course the main point is to make a correct diagnosis. The symptoms following the injuries to the abdominal viscera are usually sufficiently plain. I lay most stress upon the character of the pain. It is usually intense and paroxysmal in character. It is nearly always accompanied by vomiting.

Blows upon the abdominal wall, unaccompanied by rupture of the viscera rarely give rise to such

grave symptoms. Usually a soothing application and rest will give relief. If in spite of this simple treatment severe paroxysmal pain continues for some hours we may be sure, almost beyond doubt, that we have to deal with a grave condition for which laparotomy affords the only relief.

Should the injury cause internal hemorrhage, percussion of the dorsal gutters will give dullness and thus make the diagnosis more certain. Many such cases are lost by the so-called conservative surgeon waiting for symptoms of peritonitis. Symptoms of peritonitis mean peritonitis and the operation is then, in the vast majority of cases, followed by the usual result—death.

After such injuries the patient should be carefully watched for a few hours, and a few hours only. For my part I would rather make a mistake and operate immediately than to fail to operate in a single appropriate case. For in the inappropriate cases, a simple exploratory operation would rarely result in death, and would add but little to the gravity of the case, while delay in appropriate cases would almost certainly result in death.

I do not deny that blows on the abdomen may give rise to the described grave symptoms without visceral injury, but I do emphatically deny that such symptoms will continue for hours after the injury. I am also not unmindful of the fact that in grave visceral injuries patients have recovered without surgical interference, but I desire to ask the procrastinating surgeon how many he thinks would recover without such aid,—how many such cases he has seen? Should he tell of such cases I would be glad to ask him if he was sure his diagnosis was correct, and to give us the reason for his faith.

Cases of rupture of the liver and spleen are very much more liable to recover without surgical aid than rupture of the intestine or bladder. In cases of the former kind, (i.e., of the liver and spleen) unaccompanied by evidences of hemorrhage, an operation might be delayed many hours. In such cases the surgeon should not hesitate to operate as soon as he is well satisfied that the expectant plan will fail, and this means that he should do it before the development of peritonitis.

NECROLOGY.

Dr. Clarke of San Francisco, died Sept. 14, 1893.

Dr. George G. Shively of Waynesboro, died Sept. 20, 1893.

Dr. J. E. Roche of Chicago, died Sept. 29, 1893. The doctor's life was lost by an accident. His horse ran away and the vehicle upset, throwing him into the river. His body was not recovered for several days.

Dr. Walter Vought of New York City, died of typhoid fever September 24. He was a native of Buffalo, N. Y., and educated at Yale College, Columbia University, at Heidelberg and Vienna. He made nervous diseases the subject of special study, and was chief of clinic in that branch at the Vanderbilt Clinic. He was a member of the New York Academy of Medicine, Pathological and other scientific societies. In the summer of 1892, his name became a household word by reason of his having been appointed to the charge of the Fire Island station for cholera suspects. He was 31 years old at the time of his decease.

BOOK NOTICES.

A Dictionary of Medical Science.—Containing a full explanation of the various subjects and terms of anatomy, physiology, medical chemistry, pharmacy, pharmacology, therapeutics, medicine, hygiene, dietetics, pathology, surgery, bacteriology, ophthalmology, otology, laryngology, dermatology, gynecology, obstetrics, pediatrics, medical jurisprudence and dentistry, etc., etc. By ROBERT DUNGLISON, M.D., LL.D., late Professor of Institutes of Medicine in the Jefferson Medical College of Philadelphia. Edited by RICHARD J. DUNGLISON, A.M., M.D. New (21st) edition, thoroughly revised, greatly enlarged and improved, with the pronunciation, accentuation and derivation of the terms. In one imperial octavo volume of 1,181 pages. Cloth, \$7.00; leather, \$8.00. Philadelphia: Lea Brothers & Co., 1893.

In a recent issue we announced the early publication of the new edition of this great work and favorite American dictionary.

It now lies upon our table, and in examining it we are pleased to note, that all the old features that have made Dunglison's Dictionary so popular in the past have been retained. Many new improvements have been made, to bring the work up to date. No previous edition has witnessed so many additions and changes, in which the editor has apparently been greatly aided by the many dictionaries that have appeared since the last edition was issued.

A perusal of the book will convince any one, that the "Dunglison" will still retain its well earned place in the medical library for a long time to come, as a monument to American scholarship.

Bellevue Hospital and Its Internes.—A presentation copy of this interesting book, "An Account of Bellevue Hospital, with a Catalogue of the Medical and Surgical Staff from 1736 to 1894," is before us. It is from the De Vinne press, and faultless in its typographical dress. It is abundantly illustrated, and attractive beyond anything of a medico-historical nature that has hitherto fallen under our notice. About one-fourth of its letter-press is given up to the history of the hospital and about three-fourths are needed for the catalogue. The latter part is that which must necessarily have entailed the laborious efforts of the editor, Dr. Robert J. Carlisle, to gather together the records of a thousand or more names of practitioners who have gone forth from Bellevue's wards to the four corners of the earth. Dr. Carlisle has done his work patiently and fully, and he is to be congratulated if he has survived his labors and has his health. A number of good portraits adorn the book, among the best of which are the faces of the late Drs. Alonzo Clark and Henry B. Sands. The book is published under the auspices of the Society of the Alumni of the Hospital, which may be addressed at No. 5, West Fifty-eighth Street, New York City.

Alabama State Medical Association.—Transactions for 1893. The transactions of this Association appears in its usual well-written form, contains some excellent papers but, above all, shows the most careful organization of probably any State society in the United States. The report of the board of censors, annually published by this Association is unique. It includes the reports of the examinations made by each county board of censors of candidates for admission to practice, with the comment of the censors thereon, a roll of county societies, the annual oration and various interesting papers. The book is highly creditable to the Association and the publication committee. The secretary is Dr. Jas. R. Jordan of Montgomery, Ala.

New York State Medical Association.—Transactions for 1892. By all odds the most complete and comprehensive transactions that have reached our table thus far, are the trans-

actions of this Association, comprised in a handsome volume of 831 pages. It has been carefully edited for the Association by Dr. O. C. Ludlow of New York. The papers include the following: "President's Annual Address," by Dr. Jackson B. Andrews of Erie County. "Pneumotomy for Abscess of Tubercular Abscess and Gangrene of the Lung; Two in the Same Patient," by Dr. John Blake White of New York County. "Traumatic Osteo-Arthritic Lesions which Involve the Proximal Segment of the Ankle Joint; Their Pathological Anatomy and Treatment," by Dr. Thomas H. Marley of New York County. "Muscular Traction for Hip Joint Disease," by Dr. Thomas M. Ludlow Chrystie of New York County. "Some Recent Cases of Appendicitis," by Dr. Nathan Jacobson of Onondaga County. "Ectopic Pregnancy," by Dr. Henry D. Ingraham of Erie County. "Antiseptic Vaginal and Intra-Uterine Injections Unnecessary, if not Injurious, in the Daily Practice of Obstetrics," by Dr. Darwin Colvin of Wayne County. "The Palliative Treatment of Such Cases of Cancer of the Uterus and Its Adnexa as are not Amenable to Radical Operative Measures," by Dr. J. E. Janvry of New York County. "A Case of Puerperal Eclampsia at the Seventh Month, With a Few Thoughts from Practical Experience as to Treatment," by Dr. Douglas Ayres of Montgomery County. "Tumors of the Orbit. A Detailed Account of Nineteen Cases Illustrating the Paper on the Same Subject Presented to the New York State Medical Association at Its Meeting in 1891," by Dr. Charles Stedman Bull of New York County. "Paraplegia," by Dr. Charles W. Brown of Washington, D. C. "The Question of Maternal Impressions," by Dr. H. S. Williams of New York County. "Clinical Contributions to the Subject of Brain Surgery," by Dr. Roswell Park of Erie County. "A Plea for the Early Extirpation of Tumors," by Dr. John W. S. Gouley of New York County. "Remarks on a New Method of Intestinal Anastomosis," by Dr. Benjamin M. Ricketts of Cincinnati, Ohio. "A Report of Some Cases of Compound Depressed Fracture of the Skull," by George D. Kahlo of Indiana. "The Achievements of American Surgery," by Dr. Frederic S. Dennis of New York County. "Memoranda, Practical and Suggestive," by Dr. H. D. Judama of Onondaga County. "Acute Pleurisy," by Dr. Frank S. Parsons of Northampton, Mass. "A Clinico-Pathological Study of Injuries of the Head, With Special Reference to Lesions of the Brain Substance," by Dr. Charles Phelps of New York County. "The Etiology of Gastric Ulcer," by Dr. Charles G. Stockton of Erie County. "The Examination and Commitment of the Public Insane in New York City," by Dr. Matthew D. Field of New York County. "Mitral Stenosis in Pregnancy," by Dr. Zera J. Lusk of Wyoming County. "The Use of Electricity in Midwifery," by Dr. Ogden C. Ludlow of New York County. "The Role of Microbes in Disease," by Dr. N. B. Sizer of Kings County. "Abdominal Hysterectomy for Myoma," by Dr. Frederick A. Baldwin of New York County. "Extraction of Steel from the Interior of the Eye with the Electro-Magnet," by Dr. Alvin A. Hubbell of Erie County. "The Mental Symptoms of Fatigue," by Dr. Edward Cowels of Somerville, Mass. "A Review of Some Injuries of the Upper Extremity," by Dr. E. M. Moore of Monroe County. "Fractures of the Patella Treated by Continuous Extension; Patients not Confined to Bed," by Dr. Joseph D. Bryant of New York County. "Winter Cholera in Poughkeepsie," by Dr. James G. Porteous of Dutchess County. "Suggestions Relating to Improvement of Quarantine," by Dr. Stephen Smith of New York County. "The Limit of Responsibility in the Insane," by Dr. John Shady of New York County. "Some Personal Observations and Reflections upon Alcoholism, the Effects of Alcoholic Abuse upon Posterity, and the Treatment of Alcoholism," by Dr. H. Ernst Schmid of Westchester County. "Climatology in Its Relation to Disease," by Dr. S. J. Murray of New York County. "Pelvic Version," by T. J. McGillivuddy of New York County. "Should We Treat Fever," by Dr. S. T. Armstrong of New York County. "Brief Comments on Materia Medica, Pharmacy and Therapeutics of the Year Ending November 1, 1892," by Dr. E. H. Squibb of Kings

County. "Gynecological Hygiene," by Dr. J. B. Rogers of Erie County. "The Superior Cervical Sympathetic in Local Anæsthesia," by Dr. J. B. Rogers of Erie County. "The Hygiene of the Larynx," by Dr. J. B. Rogers of Erie County. "The Hygiene of the Larynx," by Dr. J. B. Rogers of Erie County.

The Neurology Report, by Dr. J. B. Rogers of Erie County, deceased, 1891-92. The volume is 100 pages long. It is published by Dr. J. B. Rogers of Erie County, N. Y.

The Association is also indebted to Dr. J. B. Rogers of Erie County, N. Y., for the organization of the Association for the year 1892-93. Those who adhere to the regulations of the American Medical Association have well performed their part. Dr. J. B. Rogers, M. D. of Troy, N. Y., is the secretary.

Pennsylvania State Medical Society.—Transactions for 1892. The transactions of this Society are comprised in a handsome volume of 288 pages, containing the minutes, the annual report and the papers read at the meeting. The volume contains papers by such well-known authorities as Price, Shoemaker, Roberts, Tyson, Dixon and Mills. Several of the papers are handsomely illustrated, and the book is well printed. Wm. B. Atkinson, M. D. of Philadelphia is secretary.

DOMESTIC CORRESPONDENCE.

Antisepsis as She is Taught.

Cleanliness is next to godliness.

To the Editor:—Some of the requirements of modern antisepsis, such as shaving the pubes, sealing vagina and anus, and banishing pater-familias, ante-partum must impress the veteran obstetrician much as the swallow-tail coat and standing collar did an untutored savage in process of civilization. Delighted and tractable he was until he came to put on these articles of apparel, when suddenly disrobing he resumed his war paint and feathers and with a "whoop" disappeared in the bush.

C. M. FENN, M.D.

San Diego, Sept. 18, 1893.

MISCELLANY.

The Health of the British Army.—The report of the British Army Medical Department for the year 1891 has recently been issued. The delay in its appearance is allowable when it is considered that reports have to come in from all parts of the world before the consolidation in the office of the director general can be made. In turning over its pages the tabulated statistics naturally attract our attention first; and we are gratified to find that in the presentation of our own army medical statistics our military brethren are in no ways behind those of her Majesty's service. We observe that the latter purport to give the rating of sickness under certain specified conditions of disease for the year and the average ratios for the previous ten years; but as a matter of fact the average ratios are given only for the years 1881-90, and a note at the bottom of each page of the tabulations announces that "the average ratios for ten years will be given in future years. The average ratios for the six years, 1886 to 1891, will be given in the report for 1892; those for the seven years, 1880 to 1892, in that for 1893, etc." The reports of the surgeon general of the United States army for several years back have given the ratios for the preceding decade that the value of the ratios for the year reported may be appreciated the more readily. Again, the tables of the United States reports give the data for a larger number of specified diseases than are found in that now before us. By way of illustration, the

latter furnishes us with the rates for diseases of the respiratory system in gross, while the former specifies the rates of catarrhs and common colds, bronchitis, pneumonia, pulmonary phthisis and pleurisy, and bundles up by themselves only the remaining unspecified diseases of this system. Similarly, our tables give much more information as to the prevalence and severity of wounds, accidents and injuries.

The strength of the British army was in round numbers 200,000 men; half of these men were on the home stations, and two-thirds of the other half in India. Malta and Gibraltar were the largest of what may be called the small military settlements, the former with nearly 8,000 and the latter with 5,000 men. Canada had only 1,500.

The admissions on sick report of the home service troops amounted to 772.2 per thousand of strength. This seems to intimate that there was much less sickness among these men than in our army during the same period, for our admission rate was 1364.78 per thousand; but notwithstanding their relatively small number of cases our British friends had 41.66 men constantly sick while we had only 42.01. The average duration of each case was with them 19.69 days, with us 11.2 days. It is seen, therefore, that the admission rate means little. Our medical officers place men on sick report for trivial disorders that do not meet with official recognition in the British army. The non-efficient rate, based on the number constantly sick, is the proper rate for measuring the relative amount of sickness in different armies, and as these rates are 41.66 and 42.01, our disability during the year must be regarded as practically the same as theirs, notwithstanding their smaller number of cases. Their death rate was 4.94, ours 8.06; but the latter includes the men who were killed in the Sioux campaign. Their rate of discharge for disability was 14.51, ours 17.23.

When we consider that the 100,000 men who furnished these statistics were stationed on what in this country would be called fancy duty, we have reason to be gratified with the comparison, for many of our men during the year were exposed to all the discomforts and insanitary conditions incident to a state of war. When the British troops on foreign stations are brought into the calculations the general death rate of their army rises to 9.13, and the constantly non-effective from sickness to 55.56. Their heaviest death rate was reported from the Mauritius, 25.87, half of which was caused by enteric fever. India gave 16.36, the main factors enteric fever and cholera, and the West Indies 13.69, in part due to yellow fever. The highest non-effective rate was given by the troops in the Straits settlements, 93.48, more than half of it the result of venereal diseases. India had 80.22 constantly sick and the West Indies 75.53.

But it is with the record of the home service troops that we are chiefly interested, as permitting us to compare the morbidity among our own troops with that of men who are stationed in a healthy climate and have the best medical and sanitary care. Enteric fever caused only 1.1 admissions per thousand of strength, as compared with 3.35 in the United States, but in considering these rates it is to be remembered that a large number of other continued fevers were reported in the United Kingdom many of which would probably have been called typhoid fever in this country. As in previous years, the station at which there were most cases of enteric fever was Dublin. Influenza prevailed as much in Britain as in the United States. Although the custom is generally entertained in this country that drainage and efficient cultivation have banished malarial fevers from the British Isles, we find that there were 18 admissions in Scotland, 3.0 in Ireland and 9.6 in England and

Wales. The greatest prevalence in the United States was 546.05 in Oklahoma, but the average of the army was only 62.63. If the sickness from all forms of venereal disease is taken together the British admission rate amounted to 197.4, and the constant sick to 15.34. Our figures compare favorably with these, only 72.46 admissions and 5.00 non-efficient; but if all our garrisons were in the neighborhood of cities, as are most of the English stations, it is possible our rates might be as high as theirs, for their highest admission rate, 280.0, in the Channel Islands, was nearly equalled by our recruits at Columbus Barracks, Ohio, who had a rate of 266.06. It is alcoholism, however, that must be regarded as the special vice of our troops when compared with the British, if any faith may be placed in the statistics. Only 24 admission were recorded, while the United States rate was 40.01. We know that our men go on sick report when they are suffering from the effects of dissipation, but the figures fail to give us any idea of how this may be in the English ranks. We have recognized already that their trivial cases are not taken on the sick report, and a little cerebral congestion or gastric irritability due to the conviviality of the evening before may be regarded as one of the trivial cases. The admission rate for injuries was 105.1, and the mortality .70, as compared with 248.91 and 3.02 in the United States. They had a total of 19 deaths from gunshot wounds in their 100,000 men; we had 87 among our 25,000; they had 27 deaths from drowning, we 18; they 25 suicides, we 22; all of which seems to indicate that on home service Tommy Atkins has a quieter and easier life than he would have if he emigrated and took service under the stars and stripes. Out of a total of 35,678 operations of vaccination of soldiers 68.31 per cent. gave perfect results, 18.87 per cent. gave modified results, 12.82 were failures.

Of 6,132 recruits inspected 37.88 per cent. were rejected. We are more exacting in our requirements, for of 25,050 candidates we rejected 63.84 per cent. The average British recruit is young and undeveloped, age 19.6 years, height 65.6 inches, weight 122.3 pounds, and chest measurement 33.4 inches. On account of our short term of enlistment and the inclusion of our re-enlisted soldiers in the list of accepted men, our average recruit is a much better man. Age 24.43; height 67.43 inches; weight 145.35 pounds; circumference of chest at expiration 34.16 inches; at inspiration 37.02 inches.

In the appendix to the Report Brigade, Surgeon Lieut.-Colonel J. Lane Nottter reviews the progress of hygiene for the year 1892. He speaks highly of the work of the Massachusetts Board of Health, and cites from a paper by Mr. Fuller on the differentiation of the bacillus of typhoid fever in water. The method of Dr. Theobald Smith for distinguishing the typhoid bacillus is also given. Special note is made of the efforts in France to reduce the prevalence of enteric fever in the army by the substitution of pure for polluted water, or in default of this, by subjecting the impure water to a filtering process by the Chamberland filter. Wherever an epidemic broke out the water supply was found to be contaminated. In 1867 the enteric fever cases numbered 6,881; since then they have been reduced 52 per cent. The filter is composed of Chamberland bougies, system Pasteur, placed in concentric circles in the inside of a metallic reservoir capable of receiving water under a pressure of three atmospheres. For a company of infantry a filter of twelve bougies is allowed, with a reservoir having a capacity of 150 liters. The officers of the medical department are responsible for the proper working of the filters.

Epidemic of Typhoid in Allegheny, Pa.—An epidemic of typhoid fever has broken out in lower Allegheny and invaded the Western Penitentiary. Two deaths in two days occurred in the prison. Eighteen other prisoners are in the hospital suffering with the disease and some may not recover. Outside the prison there are scores of cases. The drinking water pumped from the Allegheny River is given as the cause of the epidemic.

New Hospital at Kansas City.—The University Medical College of Kansas City, have leased All Saints' Hospital, and organized a new staff. Dr. B. E. Fryer is President of the Board of Managers.

The New City Hospital at Minneapolis was opened for occupancy October 1.

Health of New York.—During the month ending September 30, the lowest mortality thus far of the year 1893 was reached in the city of New York. The total number of deaths reported was 678, which is 53 below the average of the corresponding weeks of the past five years, and represents an annual death rate of only 18.54 for each thousand of the estimated population. Notwithstanding the generally improved condition of the health of the city, however, there was an increase of seven over the previous week in the number of deaths from smallpox, which amounted to ten. On account of the increase in this disease the health department is making use of extraordinary precautions, and has just secured from the Board of Estimate and Apportionment the appropriation of \$3,000 for the payment of fifteen extra physicians to serve in the free vaccinating corps. Dr. Nagle, registrar of records of vital statistics, reports that epidemic influenza has again made its appearance in the city, a month earlier than last year. During the week two deaths were recorded as due to this cause, and they are the first reported from la grippe, since the week ending July 1, when there were also two fatal cases. Last year the first death from it was reported October 29, and up to the close of the year the deaths amounted to twenty. From January 1 to July 1 there were 182 deaths. During the week there were thirteen deaths from typhoid fever, two from scarlet fever, twenty-three from diphtheria, four from cerebro-spinal meningitis and eight from measles.

A Simplified Formula for a Much Litigated Article.—A nostrum that has been much in the papers and much in the courts, and is nevertheless still doing a considerable business, it is said, is the subject of an exposure in the *Dentists' Circular and Chemical Gazette*. The object of the article is to present a prescription which, while not coming in conflict with the patent rights of any microbe destroyer, will have all the desired or desirable potency. It has been declared by Dr. Eccles of Brooklyn, in the journal above named, that the Kadam's Microbe Killer contains sulphuric acid for its main support in the realm of germ-slaying. The prescription, simplified from the analyses of Eccles and others, reads as follows:

Sulphurous acid, U. S. P., four ounces; sulphuric acid, commercial, four drachms; muriatic acid, two to ten drops; red wine, one ounce; water, sufficient to make one gallon. In former analyses, the muriatic acid had been found in larger proportions. That was "one of the best of the ingredients," as Dr. Eccles reported in 1889, whereas now it is almost eliminated and sulphurous acid has taken its place. Dr. Eccles states later that he is informed that the formula used by the Canadian branch excludes the red wine, one ounce to the gallon.

Pigmentation Treated by Tattooing.—According to Dr. Paschke, in the *Archiv für Dermatologie und Syphilis*, Heft. 3, 1893, tattooing may be made use of in the relief of pigmentations of the skin. The material chiefly used by him has been baryta-white, which latter may be toned to the color of the surrounding integument by a judicious admixture of browns and reds. A little experience, with a good eye for color, will bring about a considerable improvement of the unsightly parts.

Dr. Ohmann-Dumesnil of St. Louis, has shown that tattooing may be removed by tattooing. His method involves a new principle; namely, the digestion of the subcutaneous pigments by papoid. The tattooed parts having been well washed with soap and water, a bunch of cambric needles—six or eight—bound together with silk thread is used. This medical tattooing implement is dipped in glycerol of papoid, and driven with a sharp blow into the tattooed part. This is repeated over the entire stain, and must be thorough to be effective. A peculiarity about this method is that it causes no inflammatory reaction observed in tattooing with Indian ink or other pigments. Dr. Ohmann-Dumesnil considers that the digestive principle of the papoid is disseminated about the deposit of pigment thus liberating it. A portion is absorbed, in a finely divided state, by the lymphatics; another part probably finds its way into the upper layers of the epidermis and thence to the surface; and in this manner the pigment disappears.

Elected Mayor of Woodward.—Dr. Melton of Denver, Colo., was one of the "boomers" that went to the Cherokee strip, and when the land was thrown open to settlement and the people had selected their locations and erected their tents a municipal government was organized by the election of Dr. Melton of Denver, as mayor; Attorney Lame of Denver, city attorney, and a board of aldermen consisting of five members, three from Denver, and two from Texas. On Sunday two services were held, and Woodward has started on its career with as good and even better prospects than any settlement in the strip. Following precedent, a new medical society and medical journal will doubtless soon be added to the attractions of the infant city.

The Anti-Rheumatic Ring.—A writer in *Science Gleanings* says that two thousand years ago the Greeks believed that there was virtue in finger rings as against rheumatism. Galen, in the second century, gave heed to some of the popular fancies of that day, and recommended a ring of jasper with an intaglio of a male figure wearing about his neck a bunch of herbs. Marcellus, in the time of Marcus Aurelius, prescribed a ring of pure gold, with certain Greek letters inscribed thereon, to be worn for pain in the side; the circle was directed to be worn on the side opposite to the pain. The decrease of the moon was propitious to the plan of cure. "And these rings," says the writer, "had quite as much medical value as those that are now being sold for the relief of rheumatism."

Bequests to New York Hospitals.—The will of the late Hon. Hamilton Fish provides that St. Luke's Hospital shall receive \$5,000, and the Bellevue Training School for Nurses \$2,000. These are gifts additional to former ones made during the lifetime of the donor.

Fatality Following the Administration of Chloroform.—A death after chloroform occurred at the Methodist Episcopal Hospital at Brooklyn, N. Y. The patient, an adult male, had been brought to the hospital for the reduction of a dislocation of the arm, due to a fall from a wagon. Full anesthesia had not been induced before syncope set in, which could not be removed by the restoratives used.

Examinations of Manitoba University Medical Department.—The program of examinations is as follows:

Wednesday, Sept. 20—9-12 A. M. Algebra, med. entrance and previous supp.

2-5 P. M. Canadian hist. and geog., med. entrance and previous supp., chemistry.

Thursday, Sept. 21—Euclid, med. entrance and previous supp.

2-5 P. M. Arithmetic, med. ent. and Latin, prev. supp.

Friday, Sept. 22—9-12 A. M. Physics, med. ent., trig., prev. and pass.

2-5 P. M. Latin, Virgil, med. ent., French, previous studies, pass.

Saturday, Sept. 23—9-12 A. M. Latin, Caesar, med. ent.

2-5 P. M. Botany, med. ent.

Monday, Sept. 25—9-12 A. M. Grammar and rhetoric, 1½ composition, 1½.

2-5 P. M. Optional subject, poetical literature.

Dr. J. L. Wilcox of Springfield, Ill., has been recently appointed Collector of Internal Revenue for the Pekin district.

A Cottage Hospital is to be built at Woodstock, Ont., at a cost of \$10,250.

THE PUBLIC SERVICES.

HEAD-QUARTERS OF THE ARMY, ADJUTANT-GENERAL'S OFFICE
WASHINGTON, September 22, 1893.

GENERAL ORDERS, NO. 78.

By direction of the Secretary of War, upon the recommendation of the Surgeon General of the Army, the faculty of the Army Medical School, established by General Orders, No. 31, June 24, 1893, from this office, and regulations for the government of the school are announced as follows:

FACULTY OF THE ARMY MEDICAL SCHOOL.

Colonel Charles H. Alden, assistant surgeon general, U. S. Army, pres.

The Journal of the American Medical Association

VOL. XXI.

CHICAGO, OCTOBER 14, 1893.

No. 16.

ADDRESS.

INTERNATIONAL CONGRESS OF PUBLIC HEALTH.

ADDRESS OF THE PRESIDENT,¹

SAMUEL H. DURGIN, M.D.

BOSTON, MASS.

PRESIDENT OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

As co-workers in the field of sanitary science, and its practical application to the prevention of disease and death, we have again assembled from different parts of this and other countries to join hands, and to take counsel with each other.

We have met this time under most unusual circumstances, and with surroundings and conditions of world-wide interest.

The Columbian exposition marks an era in the world's history. Around us are gathered the evidences of advance in all lines of industry, of talent, and of thought. There has been a peace congress, a congress of religion, a congress of charities and correction and innumerable other gatherings for the purpose of comparing notes and showing the great advance in our civilization in all lines of thought and endeavor.

Among those who have died since the last meeting is Dr. Edward H. Jones, who for twenty-seven years occupied the position of Assistant Sanitary Superintendent of New York. He was also Secretary of the American Public Health Association for two years.

His contributions to the first three volumes of the Transactions, were characterized by care and painstaking, and of a decidedly practical character.

He was much interested in his chosen work and was a modest, upright, conscientious man.

Other workers have also passed away, and tributes to their memories will be paid by the Committee on Necrology.

AMERICAN PUBLIC HEALTH ASSOCIATION.

The great trust which this Association took upon itself twenty-one years ago has been worthily held, and the work to which it has addressed itself in the interest of humanity, has been diligently pursued. It is fitting, perhaps, at this time, when we may be said to have attained our majority in years, to take a retrospective glance of public sanitation, and to note the possible results of its application in the relief of human distress. The work of the sanitarian is manifold, and deals with the most vital of our personal and social interests. It deals with the air we breathe, the food we eat, the water we drink, the soil we live upon, and with the general welfare of mankind. It means the investigation of the rise, progress, and decline of epidemics, and a fostering growth of works and projects designed to prevent and remove the causes of disease.

AIMS OF SANITARY SCIENCE.

The sanitarian concerns himself but little with the cure of disease. The problem which he seeks to solve is how disease can be averted. The pathologist establishes the nature of morbid processes, and his investigations suggest to us the appropriate remedy. The aim of the sanitarian is to seek out and remove the cause or causes which produced these processes. It has been said that preventive medicine embraces everything which relates to the physical well-being of our fellow-men, so that it has to deal with all physical evils and, incidentally, many of a moral character. Its object is the health, and therefore the happiness and prosperity of man.

It is sometimes objected that public hygiene can not lay claim to the possession of the qualities of an exact science, that its data are too partial, its generalizations too sweeping. Unfortunately some reason for this feeling exists on account of the enthusiasm of certain writers who exaggerate what is seen, guess at what is unseen, and shape their conclusions accordingly.

True sanitary science, however, is built up slowly by patient observation of facts. Sanitary science is not altogether of modern growth. It may be said to have experienced several revivals, but its real history is almost as ancient as history itself.

HYGIENE AMONG THE ANCIENTS.

The ancients fought against evil smells as vigorously as the moderns. A process of disinfection was adopted by Ulysses, and described by Homer. Hercules too, was a practical sanitarian, but of all the ancient sanitary reformers, Moses was the most thorough and practical. He gave us the principle of the modern earth closet, although the animals of the field may be said to have anticipated him in that device. During the best times of Greece and Rome, public sanitation was much studied, and the supervision of hygienic arrangements was an office of dignity among the Greeks and the Romans. The cleansing and disinfection of streets and sewers were placed under a high officer of state, because as Justinian tells us "uncleaned and unrepaired sewers threaten a pestilential atmosphere, and are dangerous."

Sanitary science owes something to the fathers of medicine also. Hippocrates was the first sanitarian who wrote an entire book on public health, and his discourses upon pure air, pure water and pure soil are instructive reading at the present day.

It is exceedingly interesting and suggestive to find these ancient writers elucidating principles which the exact investigations of our time have demonstrated to be the true foundation of sanitary science.

In Mexico it has been shown that sanitary science must have reached a high degree of perfection in its history. Previous to the conquest of the country by the Spaniards, the towns were thoroughly and efficiently supplied with water by the most perfect sys-

¹ Read October 10, 1893.

tem; but the teachings of these early times were not permanently effective. The magnificent civil works were doomed to suffer ruin, and the world passed through dark ages of mental and physical barbarism.

The devastating epidemics of the middle ages which cut off one-quarter of the population of Europe are well known. Filth, instead of being abhorred, was almost sanctified. The monks imitated the filthy habits of the hermits and saints of early Christian times, and the early fathers commended them. Even St. Jerome used to praise the filthy habits of hermits, and especially commended an Egyptian hermit who combed his hair on Easter Sunday only, and never washed his clothes at all. Monks up to the time of the reformation thought, or professed to think that, by antithesis, pollution of the body indicated cleanliness of the soul. Practically, indeed, it might be said to have helped to it, because the odor of sanctity which infected these monks and hermits helped them to keep apart from the temptations of the world; for the world scarcely cared to come into too close contact with these odoriferous saints.

MODERN SANITATION.

The science of public sanitation as practiced in our day is a growth of recent years; a reaction from the ignorance and negligence of previous generations in the matter of sanitary administration. This reaction may be said to have dated from 1838, when the English Poor Law Commissioners instituted an inquiry into the health of towns with a view to remove by public authority some of the evils incident to poverty for which the poor are not responsible, and which they can not themselves remedy. The active movers in this work were Dr. Southard Smith, Mr. Edwin Chadwick, Dr. Arnott and Dr. Farr, and it is to their labors and testimony that much of the present enthusiasm concerning sanitary investigation and administration is due. The work begun by these pioneers has been carried on with increasing zeal from that time forward. It has enlisted the active interest of a multitude of intelligent, earnest men, who have patiently and persistently devoted their energies to the investigation of the causes of disease, and a constantly increasing interest is being manifested among the people concerning all matters looking toward a more perfect conservation of the public health.

Employers have found that there is a financial aspect to the sanitary questions of the day, and that more work and better work can be obtained from men in health than from men diseased.

Legislation has been influenced by the researches into the causes of disease, and has followed the lead of the investigators.

The schools of Europe and America have one by one added to their requirements for a degree in medicine, a knowledge of sanitary science. It is becoming more and more apparent that the first and largest interest of the State lies in this great agency of human power, the health of the people.

What practical results have followed from all this? What has sanitary science done for man as an individual and for mankind collectively?

In the first place, it can be shown that man to-day has a greater expectation of life than any of his progenitors. He may more reasonably look forward to a long life, and to a life less exposed to devastating sickness. His vitality has been expanded, his

strength increased and his days on earth prolonged.

From this brief review of the general subject of sanitary science let us turn to a more specific and practical consideration of some of its principles, and I will ask your attention for a few moments to the topic of *municipal sanitation*.

MUNICIPAL SANITATION.

The municipal health officer on entering upon his duties finds himself confronted with innumerable questions as to the sources of danger to the public health, of which he has been selected as guardian.

He first pictures to himself an ideal sanitary condition, for example: a clean, dry surface; a well-drained soil; good public and private sewerage, the immediate destruction or removal of all decomposable wastes, wholesome food and water supplies, with a sufficient equipment to preserve all of these favorable conditions, and then his work of construction and maintenance begins.

It would be impossible within the scope reasonably given to a single address to more than touch lightly upon the large number of topics, and the variety of each which falls under the care of the municipal health officer. I shall, therefore, delay you by a consideration of only a few of the more important subjects which affect the health of cities.

WATER SUPPLY AND DRAINAGE.

The difficulty of finding a pure and uncontaminated water supply in sufficient quantity to meet the ever increasing requirements of modern civilized life, has confronted every large city on the globe. With the increase of population it is not possible to find a watershed which is not more or less polluted by the wastes of human life. Our great lakes even at certain points upon their shores have become at times sources of disease. And some of the cities of the old world recognizing the difficulty of procuring waters which are not contaminated by sewage, have almost by force of necessity adopted a suspicious supply, and have trusted to methods of filtration for the removal of the disease producing elements. London and Berlin afford examples of the immunity from infectious diseases attending the use of waters so filtered. A variety of opinions is held among sanitary engineers as to the best method for sewage disposal. The opportunity for the ultimate disposal of sewage is not the same for all cities. One city has the opportunity to discharge its sewage into deep tide water under such conditions as to give rise to no evil results, while other cities are not so favorably situated. It would be a safe principle to follow, however, never to discharge sewage matter into any river, lake, or body of water which is likely to be used as a source of water supply.

DRAINAGE.

Although I am not prepared to say that through the scientific experimentation now going on in the filtration of sewage-polluted waters, the time may not come when the waters of any river or lake may be used as a source of water supply, and the sewage resulting therefrom then be returned to the streams in a state of comparative purity which will render them available for domestic uses. However much we may disagree as to the ultimate disposal of sewage, there seems to be a general consensus of opinion that the water carriage system must supercede all others in its cheapness and capacity for a rapid and safe translation of our sewage from its

initial starting point to a proper and safe outfall, where it may be disposed of without offense and danger to the inhabitants of the city.

It is generally conceded that when this material is confined within its proper channels and constantly undergoes rapid removal it is harmless, and does not deserve the opprobrious epithet which it incurs under opposite conditions, namely, when stagnating without or even within its channels.

Under these favorable conditions, the problem of the ventilation of sewers becomes extremely simple by harmless open grate covers over the manholes in the streets. The public sewers thus supplied with the proper and continuous incline to secure the rapid and continuous flow, are ready to receive the private drainage from dwellings and factories and other sources.

The question of private or house drainage is more complex, and should be constructed only under regulations prepared by competent sanitary engineers, by plumbers who have shown their competency for such work to a proper board of examiners, and have been licensed therefore. The material for this work should be strong, tightly jointed, securely trapped and ventilated above the top of the house.

With a system of sewage thus supplied, the privy vault and cesspool, which have been most serious menaces to the health of cities, should cease to exist.

It is easy to see that with such suitable provisions for the complete and rapid removal of all sewage, the escape of noxious emanations from the sewers into the streets and dwellings would be impossible.

The conditions under which sewer gases are generated and penetrate into houses are from the stagnation of sewage, by its putrefaction when the consequent generation of poisonous vapors are favored, and the absence of sewer ventilation, by consequence of which these vapors are confined and pent up, until they acquire a sufficient degree of tension to force the barriers by which we vainly attempt to exclude them from our homes. By the rapid removal of sewage, on the other hand, its putrefaction in our midst is forestalled, the generation of noxious gases within our drains and sewers is reduced to a minimum or wholly prevented. The ventilation of sewers is rendered easy and harmless, and finally such air, gases and vapors as must be contained within the sewers, being no longer confined, find an easy escape into the open air.

In the city of Boston our private drainage, like that in most cities, is unsatisfactory, and the cause of an immense amount of inspection, complaint and annoyance, and undoubtedly the cause of much ill-health. We have statute laws and city ordinances which specify the method, material and workmanship necessary for the construction of house drainage. Plans for construction and repairs are submitted to, and the work approved by, the inspector of buildings.

The board of health is called upon to find defects and to order repairs, and such repairs each year number about 4,500.

For the purpose of ascertaining to what extent defective conditions of plumbing exist, and to what extent traps are supplied, and water closets substituted for privy vaults, we have taken a large number of blocks of dwellings, both new and old, each season for thirteen years, and made house-to-house inspection, with the following results:

Want of traps, first five years, averaged	
During thirteen years	2
During the last year	22
Defective conditions of plumbing first five years, averaged	46
Whole thirteen years	30
During the last year	34
Use of privy vaults, first five years	28
For thirteen years	14
During the last year	3

This means not only a very poor state of plumbing, but a want of commendable progress in the substitution of a better condition. It indicates poor construction and inefficient repairs.

It is my opinion that the regulations, supervision of construction and repairs of plumbing should be in charge of one department. The old privy vaults and cesspools, with their accumulation of filth, which were once so common, are now rapidly disappearing from the city. Nearly seven thousand of these privy vaults have been demolished in as many years, and the few remaining where a public sewer abuts the premises are under orders to go. The yard cesspools, which are also common nuisances, are being changed from receptacles for sink and other house drainage to those for surface drainage only.

DISPOSAL OF WASTE.

The removal and disposal of refuse material has become a very serious question to the city as a corporation, and to the individual citizen. There are now in vogue several different methods for the disposal of the kitchen refuse, all of which are more or less objectionable. In one city it is carried away and dumped into the sea, in another it is collected and sold to the farmers to be fed to swine, and in another it is removed to a distance from the city and buried or consumed by fire.

In the city of Boston, where the principal part is sold to farmers, and the remainder carried out to sea, the cost of collection and transportation has reached the annual sum of one hundred and seventy thousand dollars, or considerably more than the entire appropriation for the health department, which includes the maintenance of harbor quarantine, free public baths and urinals, hospitals for contagious diseases, disinfection, public vaccination, the care of public burial grounds, the inspection of nuisances, and other incidental expenses. This large cost can not be diminished by any of the present methods in use, but must necessarily be increased by the growth of population, by hauling to a greater distance, or by the process of cremation, which is now in use in many of our cities.

It must be admitted that the storing of this material in our yards, and its subsequent transportation through our streets, creates a nuisance of a most disgusting character, and it seems to me it should not be looked upon by sanitarians as harmless, or as a satisfactory method of disposal, to say nothing of the enormous cost to the city.

It has for many years seemed to me, that the kitchen wastes should, by some special provision in the kitchen stove, be disposed of as soon as they are formed. By this means, all subsequent nuisance and expense would be avoided.

The other wastes of the city which are now dumped into the harbor, and into other bodies of water, or upon vacant lots for filling, which are largely composed of combustible material, should undergo cremation, and their ashes used for filling.

STREET ENGINEERING.

The construction and care of our public and private streets have a sanitary side to be considered, especially when we remember the considerable proportion of the area of our cities which they occupy, and the frequent unsanitary condition in which we find them. While the construction of streets is almost purely a matter for the engineer, the health officer has frequent cause to complain of their filthy condition. Most streets in all cities present a more or less unclean and offensive surface. This condition may be due to a faulty pavement, want of pavement, or a lack of care, which is supported by a popular notion that an unclean and muddy condition of the streets has no appreciable effect upon the public health. Macadamized streets where much used, are unclean and offensive most of the time.

It would be in the interest of the public health, a cleaner atmosphere, greater public convenience and economy, if all of the much used streets of our cities were paved with material which would present an even, durable and non-absorbent surface.

The private alleyways are not only disowned, but generally uncared for by the city. For the most part they are found to be unpaved, uncleaned, and a source of much complaint. Any attempt on the part of the health officer to cause these places to be cleaned by the abutters is attended with great difficulty, delay and frequent disappointment. It would be far better to place these private ways in charge of the city, and tax the people for properly paving and keeping them clean.

MORTALITY STATISTICS.

Under the head of *mortality statistics*, the health officer finds a valuable guide to important sanitary work, although it is to be regretted that much of the data found under this head is untrustworthy. These mortality tables, properly prepared will show the extent of mortality, and to what extent it is excessive in any portion of the community, and its relationship to age and nationality. They will also show us the nature and causes of the diseases which occasion the excess of deaths and to what extent, and by what means, these diseases are preventable.

This work begins with the physician, and ends with the registrar of vital statistics. Many physicians perform the duty of certifying the cause of death with great care and exactness, while others perform the same service with very little knowledge of the disease of which the person died, and with corresponding ignorance of the use and value of correct mortality statistics.

Unfortunately in many States there is no legal discrimination between the duties and privileges of the educated and the totally ignorant practitioner of medicine. The registrar who receives these certificates should be a well educated physician, with considerable experience so as to be able to reject fraudulent and worthless certificates. Every one who has had experience in the registration of mortality reports, understands how difficult it is to secure correct data from irresponsible persons. The cause of these shortcomings is partly insufficiency of diagnosis, due either to the difficulties inherent in obscure cases, or to imperfect medical training, and partly to lack of conscientiousness in the performance of a registration whose objects and importance are not appreciated.

Obscure cases will occur in the practice of every physician, and due allowance must be made, and yet after reasonable allowances have been made, there still remains a degree of carelessness for which there is no excuse.

It is a common thing to find on death certificates instead of the morbid process which caused death, such indefinite information as "disease of bowels," "disease of brain," "disease of skin," "stomach disease," "ascites," "convulsions," "dropsy," "fever," "debility," "teething," "inflammation," "infantile," "heart failure," and other unlikely causes too numerous to mention, and which ought never to be used upon the records as causes of death.

In my own city, such certificates are rejected, and a competent physician sent to view the remains, and consult the family or friends of the deceased for information, with which to make a proper certificate.

It is to be noted, however, that information gathered in this way can not be regarded as wholly trustworthy, and often results in the statement of "*unknown cause of death*."

It would be in the interest of correct mortality statistics if the registrar could be authorized, in case of insufficient information, to cause such postmortem examination by a competent physician as will enable him to record the true cause of death.

An examination of the mortality statistics will also betray the fact that we have an excess of deaths from contagious diseases and from diarrheal diseases among children, and while these facts open up a wide field of labor for the municipal sanitary officer, we shall have time to mention but a few of the most troublesome of these diseases.

INFECTIOUS DISEASES.

Smallpox, through the great discovery of Jenner, the ease of making an early diagnosis and its perfect and easy control by isolation and disinfection, is now one of the easiest and rarest comparatively of the contagious diseases with which we may deal.

Now and then our legislatures are obliged to listen to the petitions of a few anti-vaccinationists for the repeal of compulsory vaccination laws. I have too much faith, however, in the intelligence and sound judgment of our people to believe that these wholesome and necessary provisions will ever be effaced from our statute books.

We should not, however, in the absence of smallpox in our country, allow ourselves to grow indifferent to the necessity of keeping the susceptibility of our people to smallpox exhausted by means of early and successful vaccination of infants, and the subsequent and most important revaccination of adults.

The mention of cholera, like that of smallpox, strikes terror to the people of this country, and while the deaths from these diseases are infinitely small, the fear of them has served the municipal health officer in securing almost unlimited facilities for their prevention and control, which means may be largely converted to the care of other more common and destructive contagious diseases.

We have in diphtheria and scarlet fever, diseases which are not only endemic in most of our cities and large towns, and of most difficult control, but diseases for which there is as yet no known prophylactic. It is easy to say, and it is equally true, that perfect isolation and disinfection in all cases would soon annihilate the two diseases, but here is where the

great difficulty begins. We do not know where the infection is, in a very large percentage of cases, and therefore can not make anything like a complete application of our disinfecting agents.

The diagnosis of diphtheria and of scarlet fever is not always possible in their early but contagious conditions, even by our best physicians, but with the multitude of ignorant and indifferently so-called practitioners of medicine, who are called to attend such cases, and the many instances of mild attacks which do not attract attention, to say nothing of the semi-popular prejudice against the hospitals, we have the causes of the lack of information to the sanitary officer, the possession of which might lead to the control of the diseases.

These diseases are spread largely by children while in the early stages of the illness, or having mild and unsuspected attacks, and by those who are prematurely released from isolation through ignorance and fraud, and allowed in the streets and in our schools.

It would be out of place, as well as presumptuous on my part, to delay you at this time with the details of necessary public interference which would secure a mitigation of the prevalence of these two diseases. I will say, however, that I believe in early and continued hospital isolation, and that all cases should be supervised, and released from isolation only by medical officers appointed upon merit by the health authorities; the same medical officers to be inspectors of schools, in which there is much valuable work to be done in detecting the early symptoms of contagious diseases, pointing out the many unobserved and growing defects in development and disabled senses of the children, reporting to the board of health the overcrowded and unsanitary condition of the school room, inspiring an interest and pride on the part of all teachers to develop an aptitude in detecting early symptoms of disease, defective senses and deformities in children, and in developing a more popular interest in the needed reforms in school hygiene.

At a very small cost, we might bring to bear the powerful influence and unoccupied energies of a large corps of talented young physicians, aided by over thirty-five thousand teachers, for the public and individual welfare of nearly thirteen million children in the public schools of the United States.

Consumption, the most destructive malady to the human race in our country, has received the necessary attention of the bacteriologist. He has demonstrated to us satisfactorily, the cause of the disease, the methods of its transmission, and the means for its prevention.

I am sorry to say that as practical workers in public sanitation, we have sadly neglected to apply the means which we believe would prove effectual in largely abating the prevalence of tuberculosis.

The isolation of all persons suffering from consumption, would be impracticable and perhaps unnecessary, but the use of small sputa cups containing a disinfectant, at home, and bits of absorbent napkin used and securely concealed in traveling, to be burned or otherwise disinfected on returning, should at least be urged by public health officers, and popularized as much as possible.

In this way we should try to counteract the indiscriminate and disgusting habit of careless spitting in all public and private places, where the sputa are soon dried, and in the form of dust, start on the mission of deadly infection.

It is interesting in this connection, to note the fact that from experiments conducted with the tubercle bacilli, the sputa from consumptive patients have been found to retain their infective power for several years, also the fact that at a recent international congress on tuberculosis, one of the questions discussed was the necessity of obligatory cremation of the remains of consumptives.

Earth worms, it was urged, bring to the surface bacilli which infest the dead body, and in dry weather they may be inhaled in the form of dust. This, it is suggested, is the reason why the health resorts of the south of Europe are centers of tubercular contagion.

Drs. Lortet and Depuignes of Lyons, related cases of such infection, and described experiments which they made which led them to demand obligatory cremation. They mixed the sputa of consumptives in earth which they placed in pots. A month later the earth worms in them were tubercular, and the earth they passed through communicated the disease to animals.

Other experiments were made by placing earth worms on the graves of those who had died of consumption, and it is said the results were confirmatory of the possibility of contagion being conveyed in this manner.

CREMATION.

It should not be necessary to urge the sanitary claims of cremation for dead bodies before an assemblage of intelligent sanitarians. There are in this country already thirty-two cremation societies, fifteen crematories, and in the last five years there have been over two thousand incinerations.

Typhoid fever, like cholera, has been studied most persistently and profitably in connection with our water and food supplies, and we shall have the pleasure of listening to a discussion of the causation of typhoid by infected milk at this congress.

HABITATIONS FOR THE POOR.

Tenement and lodging houses are subjects for the constant watchfulness of the health officer, and they are too frequently found in an overcrowded and filthy condition. They are principally occupied by the poorest classes of people, including the newly arrived emigrant, whose habits of cleanliness are of the lowest order.

It becomes necessary to limit the number of occupants in such buildings on a rule of a prescribed number of cubic feet of space to each individual, by placards posted in each room, compelling frequent scrubbing and disinfection of floors and walls, burning much of the old bedding, frequently disinfecting the remainder by steam, watching them by night and prosecuting every violation of your proscribed rules.

CONCLUSION.

Turning in conclusion from the more onerous everyday duties of the municipal health officer to topics of greater popular interest, we find an increasing growth of public sentiment in all parts of the country favoring the municipal provision of large public parks, free public baths, small open spaces and open air gymnasiums for the enjoyment and sanitary welfare of the masses of people whose whole time is spent in the toil of our large towns and cities. Much of interest and encouragement might be said as to the immense patronage and benefit of these magnificent privileges if time would allow, but

I pass over these and other important topics which, I doubt not, will receive that careful attention and discussion their importance demands during the congress which is now open.

ORIGINAL ARTICLES.

THE TREATMENT OF GRANULAR LIDS.

Read before the Section on Ophthalmology, at the Forty-fourth Annual Meeting of the American Medical Association.

BY C. B. BLURBAUGH, M.D.

PARKERSBURG, W. VA.

Gentlemen:—As an introduction to my article, the treatment of granular lids, I will say that I live in a portion of the Ohio valley where the soil is very sandy for miles from the river on both the West Virginia and Ohio sides. To this fact I attribute, to some extent, the unusual prevalence of the disease in that locality. During the past two years I have been so unfortunate as to have had 205 cases of more or less severity to treat. Of this number 125 were treated with good results by the method I give you to-day, and the rest by all the usual plans of treatment recommended without, in some cases, the success I had hoped for. I find that Drutt, in 1848, suggested scarifying the granulations; then, after a few days, he used lunar caustic on the granulations and applied citrin ointment to the palpebral edges. In 1836, Mackintosh applied blisters behind the ears and dropped wine of opium in the eyes. Gross used Goulard's extract for awhile, but soon quit it, as he found that it encrusted the cornea and produced mechanical obstruction; he then advised shaving off the granulations and applied sulphate of copper or a solution of nitrate of silver, twenty to sixty grains to the ounce of water. Fenner used a strong decoction of phytolacca, and considered the treatment especially good where there was a rheumatic diathesis or severe pain around the eye. Dixon dusted the enlarged and inflamed follicles and papillae with sugar of lead, but relies chiefly on hygiene and tonics to improve the general health; he says of all local treatment, the application of the undiluted liquor potassæ to the palpebral granulations, as suggested by Dr. Bader, has been most successful. It seems to act by saponifying and dissolving away the hypertrophied tissue. Carter uses the *lapis divinus* daily or on alternate days according to the severity, and alternating occasionally with tannin or acetate of lead. For isolated extreme hypertrophy the actual cautery has been used with success.

The ordinary general treatment of the disease is nitrate of silver and sulphate of copper. Arlt and Stromeyer called attention especially to the fact that these remedies were not intended to chemically destroy the granulations, but were to be used to maintain a certain degree of hyperemia in order to cause their absorption. I think this important fact has, to a certain extent, been lost sight of, and they have been used to chemically destroy the hypertrophied papillae. I have seen so many ugly, thick lids, with the whole mucous surface a cicatrix, presenting the condition known as xerophthalmia, and certainly the preponderance of cases to the use of these drugs, that I have laid them aside entirely.

For local treatment the four little instruments I have here play an important part, as with them the granulations are removed.

No. 1 has a smooth edge and is used to scrape off slight granulations where there is no general hypertrophy.

No. 2 is the same general shape but has a file-like edge and is used in more severe cases.

In everting the lids we frequently find the granulations thickest and hardest to remove just where the lid curves at the edge of the cartilage; here I use the curved instrument No. 3.

Above this, still, and near the retrotarsal fold, granulations are frequently found which neither of the instruments mentioned will reach; for these I use No. 4, which has a long rake set at right angles to a shorter one, and will reach the high granulations without trouble; while the long rake is removing the upper granulations the shorter one will remove those situated on the curve. Where the whole surface of the lid is hypertrophied presenting a gelatinous, granular mass, I have had, occasionally, to use the scissors. After removing the granulations as thoroughly as possible, I give my patient a simple astringent wash, regulating its strength by the severity of the case; a lump of alum which I direct to be rubbed on the everted lid as the case may demand and let him go home. In some very kind cases I have had to see the patient but once; in a number of them two to eight visits have been necessary. In all my cases I look to the general health of the patient and, unless some special diathesis is present, I have found the best tonic to be a mixture of phytolacca and rumex crispis, especially where the cornea is involved. In the majority of trachoma cases, pannus is present to a greater or less extent. For such a condition where the cornea persists in remaining opaque, inoculation with pus from an active case of ophthalmia has been tried and with some success, as has also the jequirity bean, *abrus precatorius*, a Brazilian plant. Grüning

scrapes the cornea with a small knife, removing the opacity. Where these all fail the cornea remaining opaque and vascular, peritomy or syndectomy has been done by a number of operators. In my own practice I have used jequirity bean twice; in one case the result was all that could be desired. In the other I had to work so hard to save the eye that I have not since entertained a kindly feeling for our Brazilian acquaintance. In my other cases of pannus, from slight to total, I have had my patient spray the eye with a solution of tannin and boric acid in glycerin and camphor water daily, and in addition wash the eye twice daily with a bichlorid solution. A large number of cases of pannus vasculosa disappear when the granulations are removed without any special treatment. The results have been peculiarly satisfactory in all the cases and the point I wish to make, in closing, is the fact that I have used neither nitrate of silver nor sulphate of copper in any case. Of course I scrape off the granulations only in chronic trachomatous cases.

407½ Market Street.

DR. J. L. THOMPSON—I would like to know if when a case comes to us in the first stages we should commence hoeing and scraping at once? In other words, should it be done in the acute stage of the disease, or only after it has become chronic?

DR. SCOTT—I can see no advantage in this treatment over that of expression. It is simply carrying out the same thing, and I am sorry to say that this plan of treatment has not been satisfactory with me. I have used it fully a dozen times, but with very little satisfaction, and in each case had to resort to the jequirity to obtain the desired result.

DR. LEMOND—I think I have treated within the last year near one hundred cases of chronic granular conjunctivitis, a number of which have been treated with Noyes' method of operating. I press the follicles, squeezing the morbid contents of the parts, doing it gently but firmly. I always avoid, as near as possible, not to tear or lacerate the conjunctiva. The sooner you get rid of the spurious material the better it will be for your patient. I usually follow this operation with a mild solution of bichlorid of mercury, using it as a bath for the eye about every three hours. I also direct my patient to use hot water, as hot as can be borne, from nine to ten times a day five minutes at a time; I find it very much better than cold water in these cases. Where I have not followed with the bichlorid treatment I prescribe a saturated solution of boric acid which I think also acts nicely. Among these cases I have had the very best results from this course of treatment. I think in all cases that have assumed a frog pawn condition we should have no hesitancy in resorting to Prof. Noyes' compression; in fact, I think it is the rational thing to do. I am aware that some oppose this method of treatment, but so far as I have found, among those who oppose it are men who have done the operation possibly once and in some instances not a single time.

DR. MURRELL—In my practice I have had many cases of granular lids. I think we have more cases of this trouble and in a worse form in the South and West than in the East. The oculists being few and hard to reach they go on without treatment until the disease gets in its worst form. They come to us with lids shortened and suffering with blepharospasm and we find it necessary to relieve the pressure by performing a canthotomy; I have never performed it on any case where I have regretted it and have had as many as two hundred cases of granular lids myself during the year. The treatment used is such as is suited to the particular case. In suitable cases I use Knapp's expression

forceps principally, sometimes Noyes', but the grattage I do not like. Not every case is suited to the forceps treatment. I have cured many cases by one single treatment with the forceps, followed by the use of the boric acid solution four times daily. I then direct the patient to use hot water as hot as can be borne three times a day letting it remain for half an hour at a time. There are various other remedies we resort to but to be successful with any of them we have to first relieve the pressure on the eyeball by performing a canthotomy.

DR. DENLAVY—It is my misfortune to meet a great number of granular lids. It appears to me that there can be no law laid down as to how to treat a considerable number of them. There is a certain class that can be treated successfully by the conservative method, while there is another class in which nothing short of surgical interference will be of any effect. I use Knapp's forceps, Noyes' forceps or any forceps that I have in my case, my thumb nail or any other means by which I can destroy the granular tissue. I am not one of the number who believe the subsequent reaction is beneficial, but we can not expect to do any surgical work without this reaction. The method of surgical interference, that of making a canthotomy, as referred to by Dr. Murrell is often one of the best steps where there is pressure from the lid, and we can not do it any too early. If the granulations are at all chronic we might begin with our surgical means at once. A class of cases kept well under antiseptic treatment will give very little trouble. With regard to patients getting well with one application, we have all seen them get well with scarcely any treatment at all.

DR. FRANCE—We all have our views as to the surgical treatment, but if a case comes to us and we have it in the acute stage it seems we ought to do something for it before it finally gets to the chronic stage. About two years ago my attention was called to a paper published in the *Ophthalmic Record* by Dr. Hodges in which he recommended the following remedy for granulated lids: There are two solutions used; nitrate of silver 1 dram, water 1 dram and glycerin 2 drams, marked No. 1. Iodid of potash 1 dram, water 1 dram and glycerin 2 drams, marked No. 2. Take 3 drops of No. 1 and 6 drops of No. 2; mix well and apply to the everted lid. I am not sure whether there is anything in the iodid of silver or not, but I am sure from two years experience that in acute trachoma by the use of this remedy twice a day a cure is effected in a considerable portion of the cases within six weeks.

DR. SAVAGE—I will say that the Hodges' mixture has been a wonderfully good treatment in my hands. I hardly know how I could have gotten on without it. We not only have the iodid of silver and the iodid of potassium in the solution, but we have a third ingredient, the nitrate of potassium, as a result of the reaction. Thinking that the virtue of the mixture might be due to the germicidal effect of the nitrate of potassium, for three months I have been prescribing this alone with a view of deciding this point. My experience in the use of the nitrate of potassium alone for this period of time strengthens my belief that Hodges' mixture has for its effective ingredient the nitrate of potassium. I use it in the strength of grs. xx to xxx to distilled water 1 ounce.

DR. MENCASIER—I have seen a number of cases treated with expression and the conclusion I have come to is that Knapp's roller forceps have been better than anything I have ever seen. After the operation I give the patient a solution of boric acid and direct that it be used every few hours during the day, and also direct him to use hot applications several times daily, and have usually gotten good results.

DR. DUDLEY S. REYNOLDS—I fear the gentlemen have con-

founded widely different conditions, and have entirely overlooked the question of the stage of advancement at which the treatment begins. I use no scarification, no scraping and no cauterizations. In the trachomatous and lymphoid forms, expression by Knapp's forceps undoubtedly proves successful in many cases. The hypertrophoid papillæ of the lining of the lid and retrotarsal folds are not to be treated this way without great aggravation of the disease. In the first stages of papillary blepharitis I prefer the solution of bichlorid of mercury and chlorid of ammonium, suggested by McKenzie as a cleansing wash in purulent conjunctivitis. As the purulent conjunctivitis always precedes hypertrophy this may be recognized as an entirely rational plan of treatment, varying the proportions of the bichlorid and ammonium chlorid. I often apply the crystal of muriate of ammonium directly to the everted lid, pressing it gently but firmly for a few seconds at a time. This may be done without pain by a previous application of a solution of cocaine. In some chronic cases an ointment of the yellow oxid of mercury acts well. I know of no uniformly successful plan. I, nearly always, as Dr. Murrell has suggested, practice some modification of canthotomy in the very bad cases whether acute or chronic.

Dr. BURBACH—I think I have been a little misunderstood in regard to the use of these instruments. I do not use them in every case of granular lids, but I have not used nitrate of silver or sulphate of copper in any case. In answer to Dr. Thompson I will say that I do not do the hoeing and scraping in recent cases. I have in a number of cases used some mild astringent wash and if these granules remain I rub the lid with a lump of alum. There are a number of cases in which this is successful; but in other cases where the granulations remain I pick up my little hoe and go at it. Dr. Baker said the cases were a little more numerous in our part of the country than in Cleveland. We have in our country that light, sandy soil and I think that starts cases which develop later on into granular lids or trachoma from lack of any treatment or attention. A large number of these cases were from a portion of the State far from a railroad and where physicians were not numerous. Quite a number had been affected for years and had had absolutely no treatment. I would like to ask Dr. LeMond and also Dr. Reynolds if they have any cicatricial tissue after pressing out the granules with Knapp's forceps?

PHLYCTENULAR OPHTHALMIA.

Read in the Section on Ophthalmology at the Forty-Fourth Annual Meeting of the American Medical Association.

BY DUDLEY S. REYNOLDS, A.M., M.D.

ASSISTANT OF OPHTHALMOLOGY, OHIOHOA, AND MEDICAL SUPERINTENDENT IN THE HOSPITAL COLLEGE OF MEDICINE, MEDICAL DEPARTMENT OF THE UNIVERSITY OF KENTUCKY.

Phlyctenular ophthalmia has been so variously described by writers and teachers it would seem but fair to assume that each may have been faithful in describing that form most frequently observed in his practice. Believing no form of phlyctenular ophthalmia should be regarded as a merely local form of disease, calling for local treatment alone, I am led to introduce the subject in its clinical aspects. It is certain the herpetic disease described by Stellwag is just as much a local manifestation of constitutional dyscrasia as are the seriginous ulcers, or the more common conoidal masses of lymphoid cells described by the old writers as scrofulous and syphilitic ophthalmia. It is very important to distinguish between the phlyctenular diseases of miasmatic and malarious localities, and

those observed in strumous, rachitic and syphilitic subjects. According to some writers it would be difficult to determine the syphilitic from the non-syphilitic cases; but syphilitic keratitis rarely ulcerates, yet it is nearly always attended by photophobia, by anemia and other manifestations of disturbed nutrition. In all forms of circumscribed inflammation it may be fairly assumed the processes of zymosis are going on, fermentation being, in fact, an essential feature of all localized inflammations.

Change of residence, change of diet, in fact, any change in the modes of living result sometimes beneficially. Phlyctenular disease of the cornea, like that of the limbus conjunctivalis, fluctuates according to the state of the patient's general health and nutrition; consequently a great deal has been claimed for local treatment in such cases. In some circumscribed abrasions of the corneal epithelium a small gray speck is seen, called phlyctenular keratitis, often cured by a single drop of atropin solution, just as it would have been by a drop of boric acid solution or anything which would tend to diminish the morbid sensibility in the abraded spot. The more common types of this disease are observed in the early stages as conoidal elevations, surrounded by dilated blood vessels. The oldest cells in the cone break down first, leaving a vesicular appearance at the apex of the cone; presently the walls of the vesicle rupture and the ulcerated stage is present; meantime the eye is morbidly sensitive to light and the patient, if the disease be in the cornea, is harassed with pain and disturbances of the digestive organs with more or less loss of appetite. An aperient containing calomel followed by quinin often cures the patient in three or four days' time. I have frequently observed this course in cases which had been subjected for weeks to local treatment of calomel, mydriatics, myotics and ointment of yellow oxid of mercury, so much in vogue with some of our brother specialists.

Foreign bodies in the cornea often drop out and are washed away with the tears, leaving an epithelial abrasion which in persons of previous good health will disappear without treatment. If infection of this wound should occur the indications of this state are so marked as to mislead no ordinarily careful clinical observer. The treatment in such cases should, of course, be local and at the same time vigorous. If, however, this is observed in children with fever, or even in an adult, constitutional disturbances call for constitutional treatment independently of the disease in the eye.

It is not always easy to discover the cause of phlyctenular ophthalmia, just as it is often difficult to determine the syphilitic from the non-syphilitic subjects among the poorly nourished children which are observed at the public clinics everywhere. It is never safe to rely upon what is known as the history of the case as related by the family, and if I were not addressing myself to a body of gentlemen many of whom have at times engaged in the general practice of medicine, I should say the statements of the family physician are just as misleading and unreliable.

If your patient is the subject of inherited syphilis and has phlyctenular ophthalmia you should not be able to discover the fact by the condition of the eye alone. I have often observed phlyctenular keratitis as a complication of pre-existing interstitial keratitis.

Thus the conditions stated in the description of inherited syphilis in Mr. Hutchinson's famous prize-essay, can not apply to a very large number of cases, and especially in children whose permanent incisor teeth have not yet appeared.

That state of overloaded lymph channels, with enlarged lymphatic glands, at one time supposed to be indicative of tuberculosis or inherited syphilis, and for a long time denominated scrofulosis, is now known to be brought on by excessive indulgence in the glucose types of food; even starvation itself is attended by an abnormal increase in the lymph stream, and enlarged lymphatic glands.

The late Dr. Henry F. Formad, of the University of Pennsylvania, demonstrated certain structural peculiarities in the lymphatic system of subjects of inherited syphilis, the children of tuberculous parents, and in those with acquired struma. His researches show conclusively that some of the forms of mal-nutrition in infants result from faulty development in fetal life.

Inherited syphilis, localized zymosis, mechanical obstructions in the capillary lymph tubes of the conjunctiva may each set up local changes which pass through all the varying stages of cell proliferation, disintegration, ulceration, and partake of those characters called phlyctenular disease, because of their circumscribed nature.

Dr. J. L. THOMPSON, of Indianapolis—The causes and conditions which bring about phlyctenular inflammations vary very much. I meet with it far more frequently during the hot summer months than in the winter. Living in an inland city where we have many sultry days and sleepless nights, cases of phlyctenular ophthalmia are the bane of childhood, especially where the strumous diathesis prevails. I place no reliance in any one remedy unless it be change of climate. When my patients have the means to do so, I urge upon them a change to the lakes, the mountains or to the coast. No sooner is this change made than improvement takes place. Where my patients are poor I urge upon them to keep as cool as possible, cleanliness, avoiding indigestible food, candies and all such trash. Yellow oxid of mercury ointment in cases where the cornea is not ulcerated, and treatment to the alimentary canal when indicated. Very often does this diseased condition hang on with one relapse after another until autumn when it sets in, nor does it stop here but repeats itself the following summer.

Dr. F. C. HORTZ—I do not agree with Dr. Reynolds that phlyctenular ophthalmia is of syphilitic origin in the sense in which we regard interstitial keratitis as a local manifestation of inherited syphilis. Phlyctenular ophthalmia is undoubtedly influenced by any kind of malnutrition, and the treatment of these patients is unquestionably assisted by correcting any disorder of the digestive organs or any other condition which may affect the nutrition. But local treatment is by far the most essential measure for subduing the present inflammation.

Dr. COXON—The best treatment of many cases of phlyctenular disease of the conjunctiva or cornea is a residence in a well conducted children's hospital. Results are here obtained in a few days that require weeks or months of many of these cases. Proper food, sleep, pure air and regularity in treatment are very real factors in these results. Of course, local and general medication are helpful, but the most efficient remedy is a dose of a good children's hospital. I have found this same remedial agent a most satisfactory element in the management of many of the allied affections of the eye in children.

Dr. ZEIGLER—My experience coincides with that of Dr.

de Schweinitz. The immediate origin of phlyctenular attacks is almost always nasal, and not constitutional, as stated by most authors. Examination usually reveals associated lesions of the nostril and eye of the same side. If you treat the nose the eye will frequently recover without treatment. A simple treatment is by the nasal spray, and intranasal applications of tr. benzoin. comp. two or three times a week, applied with cotton on a wire applicator. You may use a simple wash for the eye. An ointment of hydrarg. ox. flav. may prove useful.

Gastro-intestinal disturbances may originate or exaggerate the attack, by causing reflex irritation of the nose.

I agree with Dr. Thompson when he recommends regularity of diet, and especially in children who are continually eating cakes and candies which perhaps do more harm than any other variety of food. But a worse error in diet is the coffee and tea furnished by parents to their children, which soon saps their vitality. The worst examples of this unhygienic regimen are seen in hospital practice, and my formula has invariably been "no tea, no coffee, no cakes and no candy." These alone may bring recovery. Of course the bowels should be kept regular. Salt water baths are excellent for toning up the relaxed surface of the body.

Dr. LEMOX—It seems very singular indeed that a body of men, banded together in the same work and being composed of the very best men in different parts of the country, would have such a variety of views concerning the same subject. And yet it is true.

I believe in trying to build up the general health in this phlyctenular trouble and the child, I tell the mother, should be bathed and rubbed down thoroughly twice a week, until a good healthy action is brought about by the skin, to give it good substantial diet, light supper but lots of good sweet milk. In regard to local treatment I use, usually, the yellow oxid of mercury ointment. I apply this from three to six times a week, owing altogether to the severity of the case, and if there is much photophobia and inflammatory action I prescribe also atropin, instilled into the eye, three or four times a day so as to guard against any ciliary complications.

I protect the eye with dark glasses or by keeping the child in doors during the day and have it take its exercise in the twilight of the evening. If this does not arrest the ulcer in a few days I apply directly to the ulcer, once a day, a solution of argemum nitras, neutralizing the amount that might reach the healthy tissue with a solution of chlorid of sodium.

Under this course of treatment, from one to three weeks, my patient usually gets well. I have, in a few instances, applied the galvanocautery and have got very good results from that treatment. However, in the majority of cases I think this latter treatment a little too heroic.

In applying the yellow oxid of mercury, if you will mix a drop or two of water with the same amount of mercury it gives us a perfectly smooth solution, which it is impossible to obtain by simply mixing with the vaselin.

Dr. MCKELL—I use the yellow oxid locally and have frequently had complaint from its use. In reference to the method of preparing the yellow oxid I think I can suggest something better than mixing the powder first with water and then with vaselin. My druggist for a long time used this method but at my suggestion substituted olive oil instead, which readily blends with the fatty excipient and gives a uniform ointment.

In concluding the discussion Dr. DUDLEY S. REYNOLDS said: Mr. President, I am quite surprised that Dr. de Schweinitz should have misunderstood my remarks in reference to syphilis. I am sure no one would make a diagnosis of syphilis from any peculiar appearance presented in any form of phlyctenular ophthalmia by reference to the eye alone.

I have seen cases which I felt sure were due to syphilis, but other manifestations of syphilis, so distinctly characteristic as to leave no room for doubt were present, without reference to the disease of the eye.

I quite agree with Dr. Gradle that nasal diseases are frequent complications, upon the relief of which, the successful treatment of the eye depends.

My neighbor, Dr. Thompson, points out the value of climatic changes. He frequently observes a large number of these cases in the early summer, and if he is able to induce the parents to take the child away from the city, and remain until fall, he frequently finds no other treatment necessary. I feel impressed these cases fall into the hands of general practitioners, and get quinin, iron, the iodids, baths, outdoor exercise, and the mineral waters, which, with change of diet bring on such improved states of nutrition as to completely remove the constitutional dyscrasia, upon which the local disease in the eye depends.

Dr. Connor of Detroit, expresses an important truth in his statement that hospital cases frequently relapse on returning home, and speedily recover when subjected to the hygiene and improved diet of the hospital.

Eczematous eruptions of the face, and especially about the eyelids, should be treated as complications merely, and not as causes of phlyctenular disease; the yellow oxide of mercury ointment is no doubt valuable; in fact I am sure it is in eczematous complications, and in some chronic ulcerated forms of keratitis, but those are not to be counted as ordinary types of phlyctenular disease.

The point I tried to make plain in my paper is, that all local diseases known as phlyctenular ophthalmia, not clearly due to traumatic causes, should be regarded as local manifestations of a constitutional dyscrasia, that constitutional treatment is always demanded, and local treatment if applied at all, should be mild and soothing, and never stimulating or irritating in character.

Syphilitic cases are to be known by other manifestations independently of the disease in the eye, and call for certain modifications in the constitutional treatment only.

Dr. GRADLE—A number of cases of phlyctenular ophthalmia will get well as quickly whether treatment be applied or not. In other cases local applications change the course of the disease in such a decisive manner for the better, that no doubt can occur as to their efficacy. In many of these cases where we can get a definite history we will find that the phlyctenular keratitis is preceded by a purulent rhinitis, and by proper attention to the nose the patient will often recover more promptly than if the nasal trouble is ignored. Others are caused by adenoid growths in the pharynx and the removal of same very decidedly affects the case.

While admitting the great importance of proper hygiene, rational diet, fresh air and baths in the prevention of relapses I can not say that any personal observation of mine or statements by others have ever seemed to me conclusive as to any influence of so-called constitutional treatment in the course of the attack.

Dr. DE SCHWEINITZ—If I correctly understood Dr. Reynolds that inherited syphilis was one of the causes of phlyctenular ophthalmia, I doubt if evidence to prove this assertion can be produced. In so far as the treatment of phlyctenular ophthalmia is concerned, which I prefer to denominate phlyctenular kerato-conjunctivitis, while agreeing with all that Dr. Reynolds has said concerning the advisability of good food, hygiene and proper diet, I believe local measures are of the utmost importance. I am particularly impressed with the necessity of treating the nasopharynx in cases of phlyctenular ophthalmia of relapsing character, not alone because of the almost constant associ-

ation of catarrhal rhinitis, tumefied turbinals, or adenoid vegetation, which of themselves are probably causative factors, but because their removal often suffices to remove the disease, to prevent a relapse and directly to improve the whole physical constitution of the patient. The disorders of dentition bear some relationship to phlyctenular keratitis. Borrowing an expression from Harrison Allen, I would advocate the exploration of the entire "cephalic mucous membrane" whenever this disease is manifest, and the correction of any anomalies which may be discovered.

In closing, I would refer to the relation of astigmatism to this disease as taught by Martin of Bordeaux, who has pointed out that phlyctenular kerato conjunctivitis is common at that age of life when the habits of the child become such that the effects of accommodative strain, the result of an astigmatic cornea, are likely to become apparent.

Dr. BAKER—This is an important subject to the practical ophthalmologist and is one on which I should like to see more stress laid as to the general treatment. The main thing in the treatment of phlyctenular ophthalmia is the improved general health of the child, and it is not from any direct interference with the eye. I think the best thing that can be done is to take these children away from their families and put somewhere where they can be treated and dieted just as you would have them. I believe that one of the best remedies is arsenic in small doses; one drop three times a day of Fowler's solution.

Dr. GIBSON—I wish to say only a word on this line, in regard to the diet of children. I think this a very important point, at least it has been in my experience. We should study the diet of the children; then we know how to get at the treatment. If we take away from a child what it likes it is not going to do well. We may give maltin or extract of malt to aid in the digestion of starches. Let them have their bread and potatoes. Cod liver oil will supply the food in the line of meats. You can get most children to use cod liver oil without trouble.

PURULENT OPHTHALMIA FROM THE STAND- POINT OF ITS SPECIFIC MICROBIC CAUSE;

WITH A PLEA FOR A MORE ENERGETIC, RATIONAL, ABORTIVE TREATMENT WHERE POSSIBLE.

Read before the Section on Ophthalmology, at the Forty-fourth Annual Meeting of the American Medical Association at Milwaukee.

BY ALFRED HINDE, M.D.

SENIOR SURGEON EYE AND EAR DEPARTMENT, CENTRAL FREE DISPENSARY; OPHTHALMOLOGIST TO THE NEUROLOGICAL CLINIC, AND ASSISTANT TO THE CHAIR OF OPHTHALMOLOGY IN RUSH MEDICAL COLLEGE, CHICAGO, ILL.

Progress is the watchword of ophthalmology, and we all wish to avail ourselves of the garnered harvest of the bacteriologist, and apply his well ascertained facts to the orbital corner in which we are specially interested. So much ink has been used; so many brains employed for so many years on this threadbare subject of purulent conjunctivitis that it would seem to be an act of supererogation to again ask attention to it. Yet when we consider its vast importance as a frequent cause of blindness, another modest effort to simplify the apparently different conclusions of equally authoritative observers is excusable.

Further than a bare hint that the gonococcus occasionally resides in the discharges of an efflorescent purulent ophthalmia, little is usually mentioned of this specific microbic cause in the great mass of contemporaneous literature. It would seem that since Neisser of Breslau, in 1879 discovered this

diplococcus, the peculiarities of its existence, growth, action and habitat have not been as *universally* considered by our clan as the importance of the subject demands, and to this fact is mainly answerable the diverse methods of treatment of the results of this potent microorganism. It is, therefore, in the literature of the genito-urinary tract that we find our richest rewards of observation, and in the subsequent lines the statements made are largely drawn therefrom.

As special students we must extend our observation to all the data of the microbe under consideration, for it is now scarcely contestable that the majority, if not all, the cases of purulent conjunctivitis are produced by this coccus,—as proven by careful microscopical research; and through cultivation or implantation experiments by competent bacteriologists.

This bacterium is variously described as spheroidal,³ ovoidal, hemispherical⁴ or biscuit-shaped with one surface flattened. It appears in pairs, or multiples, with the flattened surfaces toward each other, hence a diplococcus. It multiplies by elongation and division, and a single⁵ germ gives rise to a colony. In size it varies with age but its usual dimensions are about 1.6 micro-millimeters front pole to pole, and in width about 0.8 to 0.6 micro-millimeters. It thrives on mucous surfaces, and best on those covered with a cylindrical or a modified cylindrical epithelium. It stains readily with the basic anilin dyes. Pus spread out in a thin layer on a cover glass, dried naturally, passed rapidly and momentarily through a spirit flame to coagulate the albumen, immersed for one minute in a solution of 1 part methyl-blue, 33 parts alcohol and 66 parts water, then well washed in water, dried carefully, and mounted in (turpentine) balsam or glycerin, and examined with a magnifying power of 450 or more diameters will demonstrate the blue-stained microbe, if present. Steinschneider,⁶ however, regards Gram's⁷ method of staining microorganisms as necessary to the satisfactory study of the gonococcus, as a positive characteristic of it is that by this plan it is not stained, "while nearly all other diplococci found in the urethra are colored thereby." Roux⁸ also agrees with this conclusion after a study of eighty-six gonorrheal patients, and Senn adds: "The entire certainty of this test is rendered absolute by the observation of the further characteristic of the gonococci, namely, that they are found within the pus corpuscles."

Dr. J. Schutz⁹ of Frankfurt, advocates a method of staining that depends on the known resistance of the gonococcus to acetic acid after being colored with methyl-blue. Preparing the cover glass in the usual way it is allowed to remain for five to ten minutes in a cold, filtered saturated solution of methyl-blue in 5 per cent. carbolic water. It is then water washed and dipped for one moment, or until one, two, three, can be counted, in acetic acid water (acid acet. dil. mv: aq. 20 cc.) and immediately washed in pure water. The acetic acid decolorizes all other organisms except the gonococcus which remains distinctly blue: "Double staining with safranin can now be done when the gonococci and epithelial cells show a blue color, while the pus cells and their nuclei are found salmon colored."

Experimental cultivation of the gonococcus is difficult save in the serum of human blood, or less well

in animal serum, either serified.¹⁰ (See 1881, 2, 18.) (M. Huppe.) Inoculation with pure cultures invariably produces gonorrhea in man. In drying the microbe loses its virulence, and pus containing it after desiccation, fails to produce the specific inflammation either when applied dry or when moistened with water. Again, the microbe does not long retain its virulence when kept moist, yet removed from its chosen soil, for Wölander in four implantation experiments made three with pus from one to several days old and in these the results were negative. In the fourth the pus was removed only three hours before and kept at body temperature, and on the third day after implantation smarting was complained of, and two days later a typical gonorrhea developed. Two experiments in which the pus was exposed to a temperature near freezing resulted negatively. Wertheim, however, claims that their virulence is not lost rapidly in artificial culture media, for he found a four weeks' culture in human blood, still very virulent. He says the microbes must be protected against desiccation and that they develop better when protected from oxygen.¹¹ The artificial cultures grow only at body temperature and the colonies readily die off. Subcutaneous injection of gonorrheal pus in animals produced no reaction¹² and in twenty-four hours afterwards the cells remained unchanged but the gonococci had disappeared. Wertheim¹³ claims that it can produce peritonitis in some animals and he found the microbe in the walls of the abdomen, in the epithelium and connective tissue, and that it travels like other pyogenic germs by way of the lymphatics.

During research the gonococcus has been found in the urethra, bladder, kidney, perimetritic abscesses following gonorrhea, in the purulent contents of joints in gonorrheal synovitis, in the conjunctiva, rectum, uterus, cervix, vagina, vulva, and in Bartholin's glands. Its principal habitat in the pus corpuscle is more important than its diplococcus form. When implanted on the mucous membrane of the urethra or on the conjunctiva, its first growth takes place upon the epithelial layer and the deeper parts are not invaded until, by inflammatory or chemotactic changes, the intercellular cementum has been dissolved, thus loosening up the epithelia and opening up *inter* and *sub* epithelial passages. Without these changes deep or sub-epithelial infection can not occur, and Bumm¹⁴ claims that on account of the dense, compact epithelial layer of the adult vagina that a true gonorrhea of this tract is impossible, while it may occur in children. He further states that: "The stratified epithelium of the bladder is impenetrable to the gonococcus." In the incipient stage of infection the secretion is merely an exaggerated physiological one of thin mucous fluid somewhat serum-like in appearance, and containing mainly exfoliated epithelia and a few pus cells with the diplococci present on the surface of the epithelia and a few are found within the pus cells. Soon the microbe penetrates the sub-epithelial lymph spaces and the inflammation extends more deeply and after the second or third day the secretion becomes profuse and contains fewer epithelia with pus cells greatly in excess, and from 2 to 3 per cent. of the latter contain gonococci and usually two or more in a corpuscle. From now on the pus cells increase relatively in number to the epithelia, and more of them con-

tain the microbe until 20 per cent. possess them. When the subacute stage is reached the epithelia increase in number and the pus cells become fewer yet a greater proportion of the latter contain the gonococci, and more numerously. In the fourth week the epithelia are most numerous and possess the microbes while the pus cells are few. It is claimed that the cell nucleus can be invaded, and that the cell may also become distended and ruptured by the number of the contained cocci. Extra-cellular gonococci are also plentiful. Human serum we have noted as the choicest medium for their growth, hence the virulency of this infection in purulent conjunctivitis.

This bacterium produces suppuration only on continuous mucous surfaces, and it results from the irritative effect on the tissues of the absorption of the chemical substances produced by them, because pus cells emigrate to the surface before the microbes have reached the vascular layer. These same pus cells are but dead embryonal cells, or leucocytes, attracted by phagocytosis action to the infected focus in order to prevent the ingress of the cocci, or to destroy them, and by embodying them within their own walls they become ptomaine poisoned themselves and destroyed. The inflammatory exudation of cells, fibrin, and serum tends to loosen up the epithelia and aids their exfoliation. Cessation of suppuration is not synonymous with stoppage of infection for increased irritation may again arouse the chronic inflammatory process still present.

The gonorrheal micrococcus and that of purulent ophthalmia are now almost universally conceded to be identical. Prof. Haab¹⁹ of Zurich, claimed: "That the gonococcus is always present in the secretions of purulent ophthalmia and that it is never present in the simple inflammatory, or catarrhal form." Widmark²⁰ examined the secretion in twenty-four cases of purulent ophthalmia and found the cocci in most of them, free in the secretions, in the pus and the epithelial cells. He believes that during the incubative stage the microbes are only attached to the epithelial cells. This latter observation is in line with that of other examiners and most forcibly suggests an early, rational and effective treatment while the specific microbial cause is encompassable and before its ptomaine poisoning of the tissues has resulted in serious complications—due to impairment of their normal physiological resistance. Before exudative and immediate pressure have resulted in cellular necrosis and molecular death of the ocular tissues, thus producing an *infection atrium* for the entrance of the ordinary pyogenic microbes. Here the omnipresent streptococcus, and may be the staphylococcus, often take up the work of ocular destruction after the gonococcus indirectly has opened the doorway of tissue infection and reduced the resistance of the remaining cornea, and alas! they too often never end until the visual organ is utterly destroyed. That the gonococcus is a pus microbe in the usual sense is still debatable ground, yet cases have been recorded where this microbe has entered the circulation and produced metastatic abscesses after mural implantation in parts distant from the original focus. In these now numerous recorded cases of systemic infection, with septic-pyemic symptoms and occasionally fatal results, we have most often only the fever and the *hematogenous infection* produced by the absorption of the toxins of the gonococcus, followed by the localization of the floating pus microbes in the

affected tissues of various regions of the body. In short, a secondary infection. The gonococci have, however, been demonstrated in the contents of such abscesses, and are also found in the effusions into the joints of gonorrheal rheumatics, and in the blood of such patients.

This condition of secondary infection suggests the query of the harmonious co-existence of the pyogenic microbes and gonococci on the same site. Here there appears to be apparently contradictory statements.

That secondary infection can occur was first positively proven by Breiger²¹ and Ehrlich in 1882, where the pathological product of one infection aids in the localization of another kind of pathogenic germs,—one microbe preparing the soil for the growth of the other. The gonococcus it is claimed²² can so change the resistance of the tissues of the genito-urinary tract, of women especially, so that an easy invasion of pathogenic microbes occurs. As an example is given by Bumm a pure gonorrhea of the vulvo-vaginal glands which after the suppurative stage remains chronically inflamed for months and is followed by sclerosis and atrophy of the glands. But if a purulent infection is added the gland enlarges and suppurates but the contents of the abscess possess no gonococci: "The pus only contains the pyogenic staphylococcus, which has exterminated the gonococcus." Bumm also claims that a cystitis following a gonorrhea; that a suppurative parametritis after gonorrhea is analogous to a gonorrheal bubo, and all are examples of mixed infection, with pus microbes, because: "The gonococcus expends its action in the superficial layers of the mucous membrane exclusively." Delafield and²³ Prudden, however, after describing the location of the gonococcus and its subsequent inflammations write: "Under these complicating conditions the gonococcus may occur alone, or in association with the pyogenic cocci."

Prof Haab²⁴ in Zurich, often met with cases of iritis, irido-cyclitis and conjunctivitis in gonorrheal patients, "without any direct transmission of the urethral discharge" and in such no gonococci were found in the conjunctival secretion and the attacks were mild and readily overcome. These cases were examples of rheumatic and not microbial inflammations. He reports one case of mixed infection with metastatic joint abscesses, etc., with loss of one eye and great impairment of the other, together with persistent fever of many weeks' duration, and threatened death.

Dr. Bedford Brown²⁵ of Alexandria, Va., records a case of gonorrhea followed in three weeks by gonorrheal synovitis of both ankles and knees, with violent inguinal lymphadenitis of both sides, septic endocarditis, and "deep seated pain in the eye without conjunctivitis." The final result on the vision of the affected eye is not stated, and this is unfortunate because it may have been a metastatic suppurative choroiditis followed by phthisis bulbi,—a not very uncommon affection of the eye in cases of septic-pyemia arising from systemic infection with pus microbes.

A personal observation of such result may be given in the following case:

A child twenty-seven months old was taken sick with scarlet fever of mild character. Two days after the onset of the attack the left knee joint became

inflamed and the left eyeball was slightly reddened, and the submental lymph glands enlarged. The knee joint suppurated and was opened two weeks later and its purulent contents removed and finger-sized drains left *in situ* and treatment continued in the usual way. The irregular fever which varied from 99 degrees to 105 degrees F. still continued and septic pneumonia, or other focus, was suspected as the cause of its persistence, but nothing positive could be made out. At the end of six weeks from the onset of the sickness, and after the institution of marked marasmus, the left eyelids swelled up and the eyeball became red and chemotic, and supposedly painful. The appearance was that of a mild suppurative choroiditis and as the inflammation disappeared, the eyeball softened and began to shrink and nine weeks later this eye was sightless, half-sized and boggy. The neck glands did not suppurate and the septic fever gradually subsided and uninterrupted recovery occurred.

Innumerable cases of secondary infection after gonorrhea have been recorded and, amongst others of less severity, one occurred in my own practice in which, after an imperfectly cured gonorrhea, a prolonged cystitis with general septic infection followed, associated with an irremovable and intermittent fever, and exhaustion almost fatal. Recovery set in slowly on improvement of the urethral and bladder condition, the systemic microbes most probably being thrown out through the kidneys, as at no time could any local suppurative focus be outlined in any organ. One year later, after a new exposure and infection with the gonococcus, the cystitis recurred followed by septic infection and a left pneumonia of small area at first, and of insidious onset, and multiple subcutaneous abscesses, together with a profuse suppurative otitis media of the right ear. No crisis occurred but the lung inflammation continued to spread until fever and heart exhaustion, practically unaffected by all treatment, resulted in a fatal issue. In this case the gonococcus twice prepared the soil for the successful implantation *in loco* of the commoner streptococcus pyogenes—as this is the microbe, that is almost solely and invariably found in these cases.

The gonorrheal microbe, however, can not always be blamed for the production of the *locus minoris resistentia* within the ocular tissues. It is well known that floating pus microbes are present in the blood current of many malarial patients. All that is necessary for the localization of these cocci in the ocular tissues is a reduction of the normal physiological resistance of some portion of the eyeball. In these non-resistant cases this can be brought about readily by inflammatory changes and operative procedures.²⁶

Here we have an explanation of those eyes lost in a suppurative process after perfect healing of the corneal wound, subsequently to a smooth cataract extraction. We must invigorate such patients and remove these bacteria before we add operative insult to their tissues. Again, it is well known that pus microbes can long remain quiescent in old osteomyelitic foci and years later become virulent when suitable conditions of tissue injury arise for their multiplication. Have we not a parallel to these surgical cases in those old sympathetically and otherwise inflamed eyes that flare up into acute inflammation as soon as we attempt to remove the

old exudate, or perform an iridectomy. The pathosioned microbes are set free by our manipulations and are again surrounded by a suitable environment for activity and reproduction. For diagnostic purposes the presence of the gonococcus within the pus corpuscle implies a gonorrheal origin of the eye affection, and yet by so many and devious paths it reaches the conjunctiva that in some cases its source is past finding out, and we may, unfortunately, be led to question the specific character of the conjunctivitis, unless we look for and find the microorganism. For a moment we may consider the immediate and remote sources of infection. The essential element is carried to the conjunctiva usually on fingers, linen, or sponges, may be from unclean wash basin or other object in auto or other cases, accidentally or intentionally. Dr. Symes, in the meeting of the New York Academy of Medicine, Nov. 10, 1890, called attention to the supposition of the ignorant gonorrhea sufferers who, in some instances believe that they can get rid of the disease themselves by giving it to somebody else; and at the same meeting Dr. Robert Abbe said that Dr. Willard Parker had given expression to a similar observation. Twice patients of my own have asked me if this unclean intent was not a fact.

Age does not limit the possibilities of an infective source, for catarrhal inflammation, usually of gonorrheal origin, of the vaginal mucous membrane is not infrequent in the newborn, and the infant and youthful vulvo-vagina often equals the adult tract as a prolific focus of infection—the parents, or adults, being the initial source of all such cases. Moreover, the normal puerperal vaginal secretions will not produce a specific catarrhal inflammation of either the vulvo-vagina or the conjunctiva. Potts examined ninety-six cases of purulent vulvovaginitis in children, a majority of whom were under five years of age, and he believed that they were all of some specific infection, and examination of the discharge usually revealed the gonorrheal microbe, and only three cases were due to direct gonorrheal infection. Prochownik found the cocci in seventeen out of twenty-one similar cases, and in these urethritis was a prominent symptom. Sanger thinks that pyosalpinx and pelvo-peritonitis of young virgins is possibly due: "To a gonorrhea contracted in childhood through indirect infection." Spaeth in twenty-one cases of vulvo-vaginitis in girls from three to eleven years old found gonococci in the pus of fourteen, and the urethra escaped in the non-specific cases. On investigating the source he found that the mother had gonorrhea in eleven, the father in two, and violation had occurred in three of the children. Gonococci are most numerous, he says, in the urethral discharge of adult females with gonorrhea.

Dr. Van Arsdale, at the New York Academy meeting already referred to spoke of three cases in young female children, the youngest being only ten months old, and said that he saw about ten such cases yearly and attributed the infection to sleeping with parents. Dr. R. Abbe reported a gonorrhea in a boy three and one-half years old, contracted from a nurse, and gonococci were found. Dr. Hugo Felek of Buda-Pesth, before the twenty-fourth meeting of the Hungarian physicians and scientists at Kronstadt, recently held that blennorrhoea is much more common in women than is generally

supposed, and its consequences more far reaching than would appear. The women are infected in the first days of matrimony by husbands supposed to be but not actually cured of a chronic gonorrhea. He claims that the urethral inflammation may exist for some years without secretion showing, and yet will provoke in women a typical gonorrhea.

From the foregoing, the genitalia of the female would appear to be the most fruitful source of infection, and mothers and nurses the most probable starting point. On this account conjunctival inflammations in females should always be regarded with greater suspicion than in males, and I have very frequently remarked the onset of a purulent conjunctivitis in adult females commencing soon after the initiation of the regular menstrual flow—the auto-infection being most probably due to unclean fingers in infected subjects. For obvious reasons in both sexes a commencing right eye inflammation alone is more liable to be specific than simple. From such frequent possible sources of infection as we have here shown, together with the great frequency of the presence of the gonococcus in the purulent discharge from the genital canal, it would seem to be injudicious in practice to doubt the gonorrheal origin of all our cases of purulent conjunctivitis. Better for our patient's safety if we immediately consider the graver diagnosis and institute correspondingly effective measures of relief.

We have fixed the cause of the disease and located its exact position in the epithelial layers of the mucous membrane, and in those portions of the conjunctival sac covered with a cylindrical or a modified cylindrical epithelium, viz., the palpebral portions and that of the fornices, the very parts that give evidence of the greatest inflammatory reaction. Whereas the ocular or scleral conjunctiva and the surface of the cornea remain practically unaffected, because of their compact, stratified, epithelial layer, until pressure necrosis results in ulceration and secondary infection.

A good prognosis depends upon adequate treatment in the early periods of the disease, and before ocular complications occur.

Prophylaxis is advocated and abortive treatment resorted to in purulent ophthalmia of the newborn eye. Why is it not equally advisable in all eyes so affected irrespective of age? Logic and sound judgment point undeniably in such direction. In all these purulent cases there is a period of apparently simple catarrhal inflammation associated with a lacrymal-mucous secretion. A time during which the microbes are only on the surface of the epithelial cells and before the ptomaine poisoning of the tissues has resulted in attracting the emigrating leucocytes from the capillaries to the surface of the mucous membrane.

The general practitioner is the most favored in seeing these cases in this stage and, unfortunately, he fails too often to recognize its import, and either neglects treatment or prescribes the usual zinc solution, and the case is too often not referred to the specialist until complications have arisen and fear possesses the medical mind. *Without microscopic diagnosis, can one fathern the limits of a conjunctival infection when seen in the earliest stage? Any treatment, however prudent after sufficient time has elapsed, if a serious microbe has been implanted? Careful inquiry during the incubative period of these*

cases often gives positive evidence of a proximate gonorrheal focus, in men especially. Whereas, in women, beyond eliciting the information of the omnipresent vaginal discharge, an inquiry is usually negative. In busy practice we can not easily stop to stain and examine with microscope the discharge in every case of conjunctivitis. *Can we resort then to any therapeutical procedure in all such cases that will prove adequate in the purulent and at the same time harmless in the simple inflammations? We can most assuredly.* The genito-urinary surgeon has authoritatively advocated the abortive treatment of a gonorrheal inflammation in his own domain, and briefly we will refer to his conclusions. At a late meeting of the International Dermatological Congress Prof. Neisser⁶ still maintains the etiological importance of the gonococcus. That microscopic discovery of the microbe in the secretions of gonorrhea is essential to a correct diagnosis. That it is only in the first stages that the virus is accessible in the superficial layers of the epithelium and is then easy to treat. His aim is to prevent an acute changing into a chronic urethritis, and referring to treatment states: "It should therefore be commenced as early as possible after infection."

(To be continued.)

Duels Better Fought in the Early Morning.—The *St. Louis Globe-Democrat* is our authority for saying that the best time for going into battle is just before breakfast. That paper gives us the following item:

"Dr. Bernays greatly interested Surgeon General Sternberg by a proposition he laid down that when a man is shot in the abdomen shortly after eating a hearty meal the danger is much greater. 'A case of that kind should be operated upon in every instance,' said Dr. Bernays. 'If the bowels are empty, or nearly so, the same wound may be treated without operation.'"

"Applying that theory to soldiers?" remarked the Surgeon General tentatively.

"I would say they ought to do their fighting before breakfast," put in the specialist.

From time immemorial, the early morning hour has been the chosen time for the duello, for the "settlement" of private quarrels. It is a logical arrangement, and moreover the appetite for breakfast is not sharp until after the quarrel has been appeased.

METHYL-VIOLET—ITS PLACE IN THE AFFECTIONS OF THE EYE.

Read before the Section on Ophthalmology, at the Forty-fourth Annual Meeting of the American Medical Association.

BY FLAVEL B. TEEFANY.

KANSAS CITY, MO.

Since the day I first read and translated Prof. J. Stilling's articles on the subject of methyl-violet as they appeared in the *Revue Générale d'Ophthalmologie* in the year 1890, I have almost daily resorted to the drug as one of the remedies in the treatment of the various affections of the eye. For perhaps a year or more from the time this drug, as a therapeutical agent, was introduced by Prof. Stilling (as is the case with most other new remedies indorsed by authority), it was extensively discussed in all medical literature throughout the land. Many if not all ophthalmologists tried it in one form or another in one disease or another, and some were pleased with it while others were disappointed. Some were satisfied of positive results and added it to their list as a good and reliable remedy. Others were disappointed, getting as they believed no good effect so discarded, denouncing it as without merit.

When my attention was first called to the therapeutic properties of this agent, it happened that I had several patients on hand suffering from serious diseases of the eye; such as suppurative inflammation of the uveal tract, which had resisted all known treatment ordinarily used, and were marching on to the destruction of the eye. In these cases the methyl-violet certainly checked the disease and in some of the cases I believe it saved the eyes. In my enthusiasm and from Stilling's glowing account of its positive antiseptic qualities as an indemnity against all pyogenic influences, taking but the slightest attenuation to prevent all decomposition and putrefaction in any and all conditions, I employed it in nearly every affected eye that came to my public clinic as well as that of my private practice.

I tried it in all forms of conjunctivitis, in simple catarrhal ophthalmia, phlyctenular, granular and purulent ophthalmia; and in the different forms of iritis, dacryocystitis, hyalitis; disease of the cornea as the different forms of keratitis, ulceration of the cornea; in diseases of the choroid; in fact, there is scarcely a disease or affection of the eye in which I did not use methyl-violet. Not, perhaps, from my credulity or great faith in its panacea properties; and yet if it was the non-irritant and searching antiseptic that was claimed for it, taking for its predilection the germ of all activity, paralyzing and destroying all pyogenic bacteria and believing as we do that the etiology of disease is of some form of microbe, it would not be wondered at that in my eagerness I should give it a thorough trial which I did. In many diseases I have found it most efficient, while in others non-efficient, being as it were perfectly nil. In some I have found it positively harmful, acting as a decided irritant. In some cases where it has been long continued I found that it produced pain and soreness of the globe and in some instances I believe atrophy has followed in consequence of its continued use.

In most forms of conjunctivitis it is non-reliable. In purulent ophthalmia, as of the newborn or gonorrheal, its action is so uncertain as to make it unreliable; in some instances it has worked like a charm, acting as an antiseptic and dispelling purulency like

magic; in others it seems to have no effect, or if any that of an irritant. In one case of ophthalmia neonatorum where the baby's eyes were doing fairly well, but not being quite satisfied I resorted to the use of methyl-violet, suddenly the eyes grew worse and they went from bad to worse and in spite of all I could do the cornea sloughed and both eyes were lost.

I have been disappointed in its efficacy in trachoma. In this disease it is entirely nil, or has been in my hands, with very few exceptions. I recall, however, one or two cases where in trachoma with blennorrhoea of a chronic persistency, resisting all ordinary treatment, as of the trachoma forceps, brushed with the toothbrush, etc., by the use of methyl-violet a speedy cure was brought about.

There is one form of conjunctivitis and that one too that is most obstinate, frequently resisting for many months all treatment, where the methyl-violet has in my hands and with the proper systemic treatment worked speedy cures. This is phlyctenular conjunctivitis. In nearly all forms of keratitis that frequently extend over a period of ten to eighteen months before a cure can be brought about, and then at the best, concity of the cornea with myopia, I have with methyl-violet cut short the disease where the cornea was so densely opaque as not to admit of any perception of the iris or pupil. In absolute blindness due to dense opacities of the cornea, I have succeeded in clearing the cornea in as many days as ordinarily requires months with the old treatment.

In ulceration of the cornea it is a most valuable remedy, next in efficacy to the thermocautery. In suppurative iritis from its penetrability, non-irritant and antiseptic properties, as well as of a mydriatic it is of great value. In hypopyon it acts like a charm cutting short the suppuration. Soon after it is dropped upon the cornea you will see the pus in the anterior chamber taking on the violet stain, and in a few hours the pus begins to diminish in quantity and frequently have I cleared the chamber of quantities of pus in a few days, where panophthalmitis was imminent. In hyalitis and all affections of the uveal tract it is efficient, and in one case that I had diagnosed as melano-sarcoma of the choroid, the tumor by the use of methyl-violet was held in abeyance; and in one case of glioma of the retina the methyl-violet arrested the growth and as long as the child was under observation, (for several months), the tumor gradually diminished.

To sum up, the affections of the eye in which methyl-violet seems most efficient and reliable are the following: phlyctenular conjunctivitis, phlyctenular keratitis, interstitial keratitis, ulceration of the cornea, abscess of the cornea, hypopyon, all forms of iritis (especially if combined with atropia) in diseases of the choroid, as choroiditis and hyalitis, tumors of the choroid and tumors of the retina and in chronic leucoma.

Among those affections in which it seems to be non-reliable or contra indicated, are most forms of conjunctivitis, trachoma, marginal blepharitis, purulent ophthalmia and pannus.

The form of the drug that I employ is the solution 1-2000 to 1-1000 in strength; occasionally I have employed as strong a solution as 1-500. The pomade has not been at all satisfactory in my practice.

Dr. J. H. Thompson—Individually I have not used the methyl-violet, but I have seen it used in several cases, and I have never seen it used but that most valuable time was

lost. I have seen it used in eyes and they would be destroyed, not from the methyl-violet but because a disease was thus allowed to run too long for any after treatment to be effective. In general surgery as well as in ophthalmic practice such has been my observation, so I have come to the conclusion that the drug is useless.

Dr. HOTZ—Observations of this kind are absolutely worthless. To use a drug indiscriminately for almost every disease the eye may be afflicted with is not a scientific experiment but empiricism. Methyl-violet was introduced by Prof. Stilling under the name of "pyoktanin," i. e., pus killer, to emphasize its most prominent quality. Now if we wish to find out for ourselves whether this remedy possesses this pus-destroying power in so eminent a degree we must test its power in such suppurative affections which we know usually run a very destructive course. Serpiginous ulcers of the cornea, hypopyon keratitis, gonorrhoeic conjunctivitis, these are conditions where pyoktanin can show its virtues if it has any. My tests had the following results: in suppurations of the cornea it seemed to arrest the formation of pus cells; for the hypopyon and the yellow infiltrated border line of the ulcers disappeared; but in most cases the disintegration of tissue went right on leading to extensive softening, and eventually to perforation of the cornea. In one case of incipient gonorrhea of the conjunctiva pyoktanin seemed to cut short the attack; only a mild form of simple conjunctivitis followed its use. But in other cases of gonorrhoeic ophthalmia, in all cases of blennorrhoea of the membrane its applications were utterly ineffective. I have come to the conclusion that pyoktanin is a useless remedy. But when we are told it had cured a glioma of the retina, I believe the only rational explanation we can offer is that there was a mistake in the diagnosis.

Dr. TREFANY—Dr. Hotz in his remarks depreciates the efficiency of methyl-violet in neoplasms and all forms of tumors. He says that all that is claimed for it is its value as an antiseptic. We all know that this drug in our histological preparations is one of the best stains that we have, taking for its predilection the nucleus of the cell. If we concede that the drug is an antiseptic, a destroyer of microbes, I see no reason why it may not in a similar way control cell proliferation of tumors and neoplasms; at any rate, we all know that it has been extensively used not only here in America, but in Europe, and by good authority who claimed for it the power of checking if not dissipating entirely these growths. I am sure my experience will bear me out in all I have said in my paper. Very recently, within the last few days, I had a case of hypopyon where the anterior chamber was filled with pus in which I used methyl-violet with excellent results, clearing the chamber in a few days. In phlyctenular keratitis I have repeatedly used it with most satisfactory results. I have been disappointed in its use where it was most recommended by Prof. Stilling, viz.: in most affections of the conjunctiva. I have found it most useful in the affections of the uveal tract and of different intra-ocular affections.

QUIESCENT FOREIGN BODIES WITHIN THE EYEBALL WITH A REPORT OF CASES.

Read before the Section on Ophthalmology, at the Forty-fourth Annual Meeting of the American Medical Association at Milwaukee.

BY WALTER B. JOHNSON, M.D.

PATERSON, N. J.

SURGEON TO THE PATERSON EYE AND EAR INFIRMARY.

When the eyeball has been penetrated by any extraneous material the resulting injury and probable subsequent irritation and inflammation is always

regarded with the utmost concern by the surgeon in attendance. Even if the particle comprising the foreign body is very minute, if the impact has been sufficient to cause it to penetrate the walls of the eyeball and it has passed within the globe, it is a grave and serious condition. The prognosis is nearly always unfavorable, as it may immediately become a source of severe suppurative inflammation resulting in destruction of the eye, necessitating its enucleation, or if allowed to remain may eventually result in disease of the injured eye, or possible sympathetic irritation and inflammation of the fellow eye. Should a foreign body have entered the globe and only a moderate inflammation result, the question of its possibly becoming encysted and remaining quiescent, presents itself for consideration, and unless the location of the injury and the position of the foreign body should preclude the possibility of strenuous efforts resulting in a successful termination, or delay should endanger the fellow eye, all eyes should be given an opportunity to become quiet.

The eye should be treated in all cases of foreign body with antiphlogistic medicines and applications, and general medications should be administered, when indicated; the object to be attained being the preservation of the eyeball even though it is almost certain that the eye will be sightless. Should the possibility exist of sufficient sight being retained to render the eye of any service to the patient, the efforts to quiet it should be continued as long as there is any probability of the inflammation subsiding; for, a natural eyeball, if not unsightly or a constant menace to the fellow eye is infinitely preferable to an artificial eye which is always a source of discomfort, and even if most carefully matched and constructed, somewhat unsightly, in addition to being a constant expense to the wearer.

The question of the possible after effects of a present foreign body is of importance and the many cases reported in which even very small particles of steel have, after years of quiescence, become a source of such severe irritation that the fellow eye has become diseased, or an enucleation of the eye rendered necessary, have had a tendency towards preventing protracted efforts to save eyes which seem to be too severely injured to undergo a satisfactory reparative process. If a patient carrying an encysted foreign body can not at any future time be easily reached, or may pass entirely from proper observation in case of subsequent irritation, as, under such circumstances there is a decided objection to the continued presence of a foreign body in the eyeball, the desirability of efforts at its removal by operation or even, if necessary, the enucleation of the eyeball itself should be carefully considered. The operation for removal of foreign bodies by the magnet has been performed in a large number of cases; it is, however, only moderately successful. It is an extremely dangerous operation and so serious a procedure that it frequently induces severe suppurative inflammation and subsequent loss of an eyeball which might under more conservative treatment have been saved.

The time required for an inflammation resulting from the presence of a foreign body in the eye to subside is frequently a matter of great importance, especially to a patient who has himself and others dependent upon his daily labor for their support.

In such a case where the time would be too long, extending over a period of weeks and perhaps months before the eyeball would quiet, and if the eye were so severely injured that it would be sightless and there were some danger to the fellow eye, immediate enucleation would be a perfectly justifiable procedure. The cases reported are presented for the purpose of illustrating the manner in which foreign bodies may enter the eyeball and become encysted in different localities, remaining perfectly quiescent and apparently no menace to the integrity of the globe, the sight of the fellow eye, and even in some cases the sight of the injured eye itself:

Case 1.—D. F., age 30; Irish, machinist; July 12, while working at his trade was struck in the right eye by a piece of flying steel. When first examined he had a severe iritis inflammation and a scar on the cornea, temporal side, near the limbus. The iritis responded readily to treatment by atropin and a leech. The eye quieted and was perfectly comfortable. There was no idea of a present foreign body and the patient was confident that there was nothing in the eye. He had no discomfort; his vision was normal.

September 1.—Again applies for treatment stating that one week ago his right eye became red and painful and had a feeling of scratching as if something was in it, with blurring of the sight and severe headaches. These symptoms had gradually increased until present time. On examination severe inflammation with sub-conjunctival infection, and a small black speck on the globe in the temporal region were observed; the foreign body, a small piece of steel, presenting near the limbus cornea in the supra-temporal quadrant was removed with some difficulty as it seemed to be tightly imbedded in the ocular tissues. It was one-eighth of an inch in length and very thin and sharp pointed. The irritation readily subsided under cold bathing and atropin, the eye became perfectly normal and the vision equally as good as that of the other eye.

Case 2.—J. R., 44; foreign body encysted in iris May 5, 1893; while working at his trade, machinist, a small piece of steel flew from the hammer and entered eyeball lodging in iris. First saw patient Tuesday, May 9. At that time the eye was congested and there was a small white fleck on the iris below. Had some pain; he could see well; ordered atropin; the pupil responded readily and the iritis gradually disappeared. May 15. Has no pain and very little redness; his eye feels well; ordered him to remove bandage and wear shade glasses. Atropin was discontinued and on May 22 there is no redness. The pupil is coming down and the foreign body is evidently encysted being covered with a white exudate. There is a very slight indentation on the edge of the pupil above the body; the vision is normal.

Case 3.—P. W.; steel in eyeball; one week before he applied for treatment while working at his trade, a machinist, a piece of steel flew and entered the right eyeball passing through the cornea and iris just below the pupillary margin and through or into the lens. The steel can not be seen either by direct illumination or with the ophthalmoscope. The lens is somewhat opaque and presents a glistening reflex. The pupil is slightly dilated, the tension of the eyeball very slightly increased, has had slight pain, but there is no discomfort at present and no inflammatory symptoms. The vision was 1-10 three weeks after the injury and on last advice had remained practically the same since time of injury until his death three months ago, never having caused him any discomfort, either in the injured or the fellow eye.

Case 4.—F. G., applied for treatment of an iritis, which he stated he thought might be the result of a foreign body which entered the eyeball twenty years before this time; he complained that he had on several occasions had attacks similar to the present inflammation; the pupil dilated considerably under atropin but was irregular. On the temporal side there was an iridodialysis which could be readily illuminated, and directly behind the opening there was upon the fundus a large, white plaque about the size of a pea. The vision in the eye was impaired being about 1-20. The iritis responded to treatment and the patient passed from observation still carrying the foreign body.

Case 5.—J. F., age 47. Seventeen years ago received an injury from flying steel in the right eye; the steel passed into the globe in the ciliary region on the temporal side of the eye. The sight was immediately lost and never returned.

There was no opacity of the lens and no spot or plaque could be seen on the fundus to indicate situation of the foreign body. He has had occasional attacks of neuralgia in the right eye but never any inflammation. He was myopic before the injury, but to the sight of the left eye, as never been affected as a result of the injury. On Thursday ten days ago he had a severe attack of neuralgia in the left eye which was the first he ever had in that eye. On examination there was no apparent disease of that eye. R. V. O. L. V. = 20/100 with — 1-15 = 20/20.

Case 6.—W. P., age 30, machinist. One month before presenting himself for treatment and while engaged in turning on a power lathe, a splinter of steel flew from the tool striking him in the right eye, and as he thought falling to the floor. He had no pain, redness or swelling and did not notice any feeling of discomfort at any time until the third day after the injury, when he thought that his sight in the right eye was diminishing slightly; from that time until date of first visit one month after the injury there has been absolutely no symptoms present, except a continued falling off of the vision in the injured eye. R. V. = 2-7. No improvement with glasses. L. V. = 20/20. By ophthalmoscopic examination and direct illumination a small piece of steel about the size of a pin head is observed situated in the lens above and towards its supra-temporal border, directly in front and somewhat below this point a corneal scar indicates its point of entrance; the loss of vision is due to opacities of the lens. September 15, 1884. The eye has given him no discomfort but the vision has steadily diminished until present visit when he only had perception of light. The lens is entirely cataractous and milkwhite in color. June, 1893, on examination; R. V. = 20/15 with — 1-3 1-2. The lens is entirely absorbed; the fundus on ophthalmoscopic examination is seen with perfectness with — 1-4. The foreign body can not be discovered it probably having sunken down close behind the iris. He never has had any discomfort of any kind and reports the eyesight in his injured eye of great service in discerning objects appearing on that side.

Case 7.—C. A., age 44. While hunting on Oct. 29, 1882, and one hour before presenting himself for treatment he received a wound in the right eye, scattering shot from the gun of a companion having struck him. The shot used was bird shot No. 6. It grazed the upper lid and entered the eyeball just at the limbus of the cornea leaving a small crescent shaped cut upon the globe. There was a considerable hemorrhage into the anterior chamber. There is but little swelling or irritation. Ordered atropin and cold water bathing. R. V. = perception of light. October 30 on the day following the injury. R. V. = ability to count fingers at 6 degrees. A new sub-conjunctival hemorrhage has occurred near the wound. The hemorrhage in the anterior chamber and also the sub-conjunctival hemorrhage were gradually absorbed; the slight inflammation subsided and the vision improved, the patient remaining under treatment for two weeks. When an ophthalmoscopic examination could be made no foreign body was located; there was a small plaque on the fundus in a direct line with the wound in the globe anterior and the possibility of the shot having passed entirely through the eye presented itself for consideration. The vision was still impaired when the patient ceased his visits.

July 24, 1891. Eleven years after the injury the patient was sent for and examined with the following result: he was unable to say which eye was injured and stated that he could see as well with one eye as the other. R. V. = 20/30; 1-36 = 20/20. L. V. = 20/40 = 1-36 = 20/20. He has never had any discomfort since the original inflammation subsided. The vision in the injured eye is better than the other eye when not using glasses. The location of the foreign body is questionable, it probably having passed through the globe into the orbit behind the eyeball.

Case 8.—E. G., July 10, 1886, while celebrating the Fourth of July, was struck in the right eye with some powder grains, a cannon, having prematurely exploded. The grains of powder passed through the cornea and iris and into the lens causing a traumatic cataract. The eye was still inflamed on July 19 when first seen; it quieted nicely under treatment and by August 2 was perfectly comfortable, although the corneal wound was still open at times and there was an occasional escape of aqueous. The lens remained cataractous, the wound of cornea closed and the vision was only perception of light. There has been no subsequent discomfort. May, 1892, when last seen the eye remains sightless.

Case 9.—J. McD., Oct. 24, 1887, was struck while working

as a laborer in blasting rock, by a piece of steel from a drill; the steel passed through the cornea and sclerotic at the limbus; a well marked inflammation developed with suppurative choroiditis. Enucleation was advised, but the patient declined to have the eye removed; after remaining in the hospital five weeks the pain and inflammation had entirely disappeared. There was tension of the eyeball and apparently an oncoming phthisis bulbi; there was only perception of light. On ophthalmoscopic examination the field presented a semi-organized exudate filling nearly the entire half of the vitreous, evidently the seat of the foreign body; the exudate on last examination still had a reddish tinge resulting from the blood coloring matter not yet absorbed; the eyeball is quiet and comfortable and there is no irritability of the fellow eye. The steel can not be seen, being probably concealed in the exudate mentioned above.

Case 10.—July, 1888, W. M., was engaged in firing a cannon on the Fourth of July; the concussion of the ramrod exploded the charge of powder prematurely; he was standing in front of the cannon and the charge shot into his face, filling both eyes with powder and pieces of grass and weeds which he was using as wadding; both eyes were injured and there were dozens of particles of powder and stubs of grass and weeds removed from them. The orbital cavity was literally full of such particles, which were lodged in the conjunctiva. His left eyeball was severely lacerated, and the right cornea had perforating wounds through which cannon powder had passed. The resulting inflammation was so severe that the enucleation of the right ball seemed absolutely necessary; the possibility of saving the left eyeball seemed very slight. Under active antiphlogistic treatment the inflammation gradually subsided; there was no light in either eye at first, but ten days after the injury he was able to count fingers with the left eye. No sight in right eye which was diminished in tension. Present condition, June 1, 1893, phthisis bulbi of the right eye which is considerably sunken and has cicatricial contractions. He never had any pain since the original inflammation subsided. The left eye has a large symblepharon on the temporal side and is discolored by powder stains; the cornea is clear showing two scars where grains of powder, which are lodged in the iris entered; the pupil is mobile; there are some opacities on the anterior capsule of the lens. There is a long narrow choroidal plaque extending from the temporal side of the optic nerve to the extreme limit of the field, undoubtedly due to rupture of the choroid from the force of the blow. R. V. O. L. V. 20-200; no improvement with glasses. He has a sensation of light in the left eye which constantly flutters before the eye either night or day, seen even when the eyes are closed. He describes the light as a black center surrounded by moving light, no doubt due to the blind spot in the field of vision caused by the plaque at the seat of the choroidal rupture. He was at first troubled with rainbow light flashes, which would circle around and then burst, but as time passed he sees less of these; he thinks his eye is stronger than it was. He has no dizziness such as he constantly had for two years after the injury. No intolerance of light except in the early morning after working all night; he is employed as a night watchman and has been since the time of the injury.

Case 11.—July, 1889, W. S., while celebrating the Fourth of July was shot in the eye, the powder passing into the eyeball, penetrating the lens, and causing a traumatic cataract; he had a severe iritic inflammation which finally subsided and the eye became comfortable but remained sightless for six weeks after the operation, when he ceased his visits. He never, as requested, came back for future examination.

Case 12.—July, 1892, P. H., while celebrating the Fourth of July was shot in the face, a small cannon loaded with blasting powder having prematurely discharged; two grains entered the eyeball and lodged in the lens passing through the cornea and iris. The eyeball was excessively inflamed and the pupil contracted, the lens cataractous and a considerable deposit of plastic material in the field of the pupil. The inflammation subsided after six weeks of treatment and he was discharged with a fairly comfortable eye; his vision was only perception of light. He passed from under observation never returning for examination.

Case 13.—W. C., while celebrating the Fourth of July a cannon loaded with blasting powder was discharged by a companion, and the powder entered the left side of face and eyeball, passing into the chamber of the vitreous. At first there was but slight irritation and the vision was 2-5; the grains of powder which could be seen on ophthalmos-

copic examination gradually assumed a yellowish cast and increased in size until as large as a mustard seed; they presented a peculiar fuzzy appearance on either direct or oblique illumination. The vision was reduced to fingers at eight feet, the inflammation finally subsided, and one month after the injury the vision was 1-2. There was no further pain or irritation.

Case 14.—I. E., while at work in shop was struck in the eye with a flying piece of steel which entered the eyeball and lodged in the fundus causing a number of hemorrhages, forming a large stellate hemorrhagic spot on the retina. He could see one week after the operation to count fingers at twenty feet. He was under observation for three weeks; his eye having quieted, he was discharged. His vision was 1-4. He never returned to report the subsequent condition of the eyeball.

Case 15.—C. B., a machinist; while striking a chisel a piece of steel flew from the head of his hammer and penetrated the eyeball, passing through the cornea, iris and lens, and lodging in the fundus at a point directly opposite its point of entrance. There was considerable resulting hemorrhage into the vitreous and some hemorrhagic spots on the choroid to indicate the point of impact of the foreign body, which could not be positively demonstrated by ophthalmoscopic examination. There were no opacities of the lens, although the foreign body had passed directly through it. On examination on the day of the injury there was considerable loss of vision; the point of entrance and the course of the body could be demonstrated; the eye pained but little, was slightly red and the pupil did not respond readily to light; the blood in the vitreous somewhat obscured the point of lodgment in the fundus. The pupil dilated readily; the inflammation quieted and there was very little discomfort during the two weeks which he remained in the hospital. June 2, 1893. Has recently had some neuralgic pain in the injured eye, which has gradually grown blind and he can not on this date see anything but shadows. The ophthalmoscopic examination shows the pupil slightly dilated and regular. An extensive retinal detachment around the point where the foreign body had lodged; a line of opacity through lens indicating the course of the foreign body. The pain in the eye and the complete loss of vision has occurred during the last three weeks, the eye having been comfortable previous to this date. Enucleation was advised. The vision in the left eye is 20-15, but he states that he has difficulty in locating objects and thinks he can not see as well as he could with the left eye before three weeks ago when the pain and loss of vision occurred in the injured eye.

THE RESULTS OF THE USE OF THE ELECTRO-MAGNET FOR THE EXTRACTION OF FOREIGN BODIES FROM THE EYE.

WITH A REPORT OF TEN CASES.

Read in the Section on Ophthalmology, at the Forty-fourth Annual Meeting of the American Medical Association.

BY C. BARCK, M.D.

ST. LOUIS.

In the history of the use of the magnet on the eye we can distinguish two phases: 1, the use of the common magnet; 2, of the electro-magnet. The first one dates back as far as two hundred and fifty years ago, when Dr. Fabry of Cologne, used a magnet to remove a piece of iron from the superficial layers of the cornea. In 1842 Dr. Meyer from Minden (Germany), used a magnet, carrying thirty-two pounds, to remove a piece of steel out of the interior through the scleral wound. The first one who made a section through the sclera in order to remove a piece of steel with a magnet from the vitreous was Dr. McKeown of Belfast in 1874. In 1875 Hirschberg of Berlin, made a similar trial without result. These are the instances of the use of the common magnet we find in literature.

The second phase begins with the construction and introduction of the electro-magnet by Hirschberg in 1879. Since this time its use has become universal and the literature on the subject quite extensive. In

the instrument made by McIntosh, although more neat than the ones I have seen abroad, I found it necessary to have the points made somewhat longer. The battery must be powerful enough to enable the magnet to carry at least half a pound, and lately even a much stronger current has been recommended.

The cases in which the use of the electro-magnet is indicated, can be divided in two categories according to the location of the foreign body in front or behind the posterior lens-capsule. Those of the first, comprising the minority of the cases, are and have been within our reach by the ordinary methods; removal with forceps or other instruments, iridectomy, extraction of the traumatic cataract enclosing the body. But the extraction with the electro-magnet is easier, more rapid and we can for instance remove foreign bodies situated upon or in the iris without mutilating this organ.

All the cases where the foreign body penetrated beyond the posterior lens-capsule, were formerly considered beyond the scope of conservative treatment. This is the special sphere of the electro-magnet. For the scleral incision I used at first Graef's knife but prefer now a Beer's knife, which makes at once a section of the proper length. I thrust it directly through conjunctiva and sclera in the direction of the supposed location of the foreign body, making a kind of pathway in the vitreous too. The selection of the point of incision depends entirely on the calculated seat, on the determination of which I shall dwell later. The external muscles must of course be avoided. The loss of vitreous is exceedingly small, if there is no improper manipulation; frequently none at all. Hirschberg recommends chloroform-narcosis. I have operated in a number of instances under cocaine and find it just as expedient as for cataract extraction, children excepted.

The results are divided by Hirschberg into:

- 1, Good results, with maintenance of good vision;
- 2, moderate results, some vision being saved;
- 3, preservation of the eyeball;
- 4, failures.

The result depends upon:

- 1, The size and weight of the foreign body;
- 2, its septic or aseptic condition;
- 3, the correct diagnosis as to the location.

Ad. 1.—The foreign body can be called small when its weight is below 30 mgrs. Here the removal even quite a time after the injury might be crowned with a good result. If of medium size, weighing between 30 and 150 mgrs., then a primary operation only, within the first twenty-four hours will be successful. If the weight of the entering body exceeds 150 mgrs., the damage done to the structures of the eye will be too extensive to save some vision; sometimes even the preservation of the eyeball is impossible.

Ad. 2.—If the foreign body has been septic, suppuration of the vitreous sets in within twenty-four to seventy-two hours after the injury and the operation can then of course not prevent the loss of the eye. The possibility of such a condition is an indication to operate as early as possible.

Ad. 3.—The diagnosis must ascertain the presence of a metallic body in the vitreous and furthermore if possible its location. This depends mainly on the transparency of the media, especially of the lens and this again on the time which has elapsed since the injury. In the rarer instances where the foreign body enters through the sclera so far equatorial as not to injure the lens, it is of course less important. As

long as the media are clear, we can diagnose after dilatation of the pupil, the foreign body and its seat with the ophthalmoscope.

A precise idea of the situation is most important. The advice to operate under guidance of the ophthalmoscope is correct theoretically but deficient practically. I had a small mirror made to fit into the head band for the otoscopic reflector but abandoned its use. In the calculation of the seat first the meridian is determined. Then the distance from the corneal margin is measured upon the basis: first, that the most extreme point of the fundus we can see, is about 8 mm. distant from it; second, that every optic disc diameter corresponds to 12 mm. Furthermore an examination with the perimeter serves to control the calculation. The scotoma, caused by the presence of the foreign body, is transferred to the retina according to the measurements laid down by Donders in Graef's Archives (Vol. xxiii, 2, pp. 255).

It is different, if we see the cases for the first time some days after the injury when the lens has become more or less opaque. In moderate degrees we might still discern the deeper seated opacity, extravasation of blood or metallic reflex. After the lens has become totally cataractous this is impossible and our judgment of the probable seat rests then upon the anamnesis and especially the direction of the successive wounds in the cornea, iris, anterior and posterior lens capsule. The best results are obtained in cases which are operated upon within the first twenty-four hours. Moderate results are due partly to the injury done to the retina and choroid, especially where the foreign body happened to strike the region of the macula lutea, partly to opacities of the vitreous. Too much fishing in the vitreous with the magnet is always detrimental to the sight, causing shrinking of the vitreous and detachment of the retina. They are the cases of the third class, where the eyeball only is preserved. But even this result is a gain as many people regard the loss of an eyeball as a serious mutilation.

The failures are due to:

- 1, Too large a size of the entering body;
- 2, a septic condition of it;
- 3, the impossibility to remove the foreign body because the magnet did not find it or because it was too firmly imbedded in the walls of the fundus.

Eyes where operations in the vitreous have been performed should be kept under a close and long observation. Hirschberg rightly insists that no statement as to the final result ought to be accepted until at least one year after the operation has elapsed. I, therefore, report only my first ten cases, omitting three occurring during the last year. In two the foreign body was located in the anterior half of the eyeball.

Case 1.—M. B., 22 years old. Injured two days previously. In the left eye a fine scar in the cornea below and somewhat in the pupillary area. In the outer inferior quadrant of the iris, near to the pupillary margin, a small metallic body could be clearly recognized by focal illumination. It was imbedded in the tissue, a small portion of it projecting. Pupil irregularly contracted. Under cocaine, corneal section downward and outward. The introduced magnet attracts the piece at once and brings it forth. After atropization, the anterior lens capsule was found intact. Normal healing with a round movable pupil. Vision 20/30, owing to the ciliary involving the pupil. Without the magnet this case would most probably have required an iridectomy.

Case 2.—L. O., 11 years old. Injury same morning. Right eye. Corneal ciliary two lines long outward. Corresponding perforation visible in the iris. One-third of anterior

chamber filled with blood. After repeated use of atropin during two hours, pupil sufficiently dilated. A black dimly reflecting foreign body could be diagnosed in the outer half of the crystalline lens. Expectative treatment during three weeks, after which time the lens was sufficiently opaque. Iridectomy upward and outward. The piece of steel follows easily the introduced magnet. Removal of the cataract as usual. Normal healing. Secondary cataract operation later. Final result, vision 20/70 with +11.0D. In this case, the same result could have been attained by the ordinary method. The use of the magnet seemed to me of advantage.

In the other cases the foreign body entered the vitreous chamber. I shall give them in chronological order:

Case 3.—L. M., 30 years old. While striking the back of a hatchet with a hammer, the day before, a piece struck his right eye. Pain in the night. Eye moderately injected. In the upper outer quadrant of the cornea a linear ciliary one-half line long. After atropinization, a corresponding wound in anterior lens capsule near the equator was seen. The ophthalmoscope reveals, if the patient looks down, a roundish opacity in the vitreous with a metallic reflex from its center, apparently not far behind the posterior lens capsule. Fundus otherwise clear. Operation same day under cocaine. Scleral section between superior and external rectus. On the third introduction of the magnet it brought forth a minute piece of iron. No loss of vitreous. Conjunctival suture. Healing process normal without pain and very little irritation. Vitreous at first cloudy, then clearing up. Traumatic cataract did not follow. Dismissed the 15th of December. No injection of eyeball. Vision 20/40. On the place of the foreign body an irregular opacity of vitreous with corresponding narrowing of the visual field. Status the same two years later.

Case 4.—Young man from the country, seen in consultation with Dr. Williams of St. Louis. Chip of iron had entered the eye two weeks previously. Traumatic cataract. Fundus not visible. Scleral section between inferior and external rectus. The foreign body could not be found with the magnet. The eye was afterwards enucleated by Dr. Hotz of Chicago.

Case 5.—L. S., 27 years. Injury three hours previously while working on the rim of a barrel. Right eye. In the inner lower quadrant of the cornea a closed wound one line long. In the same direction in the iris an oblong perforation reaching close to the pupillary margin. Pupil dilated after one and a half hours. Wound in anterior as well as in posterior capsule and the way of the foreign body through the lens in form of an opaque streak clearly visible. In the vitreous near to the retina a gray-yellowish, sharp circumscribed opacity, the size of the optic disc. From the center, a metallic reflex. Operation same morning in narcosis. Incision with a Graefe's knife in inner lower quadrant 3mm. long. On the second introduction of the magnet the metallic body springs to it with a loud click and is easily extracted. Weight, 15 mgrs. Healing of the wound regular. The development of the traumatic cataract caused for a time glaucomatous symptoms. After its resorption the eye was found blind in consequence of detachment of the retina.

Case 6.—Young man, seen November, 1889. Injury three days previously. Corneal wound. Lens nearly totally opaque so that nothing of the fundus could be seen. In the grayish lens substance there is a sharply circumscribed black spot which looks like a foreign body. On the ground of the possibility of this location the section was made in the cornea. The introduced magnet proved the fallacy of this supposition and it was then introduced deeper through the lens into the vitreous. The foreign body could not be found. The patient did not return, and I do not know what became of him. The eye must of course be counted as lost.

I would like to mention here that a small oblong transparent portion in an otherwise opaque lens looks just like a foreign body, and is highly deceiving. The only difference is the presence or want of a metallic reflex. If this is wanting the location of the foreign body should always be supposed to be in the vitreous chamber and the scleral section ought to be made.

Case 7.—O. R., 10 years old. Right eye received injury seven days ago. Horizontal scar in upper inner quadrant of the cornea one and a half line long. Behind it, perfora-

tion of the iris. Lens nearly completely opaque, but the wound canal from anterior to posterior lens capsule and in a downward direction plainly visible. Farther back in the vitreous there is a dark spot with slightly metallic reflex just perceptible. Location of it impossible. Operation the next day under cocaine. Owing to external circumstances I decided to remove in the same operation the cataract and entered therefore with the magnet, after a corneal section downward and extraction of the cataract through the pupil. I proceeded the same way in Case 9. But although the result in this case was favorable I can not recommend the procedure. It is much more difficult to manipulate with the magnet from a corneal than from a scleral incision, and the extraction of the cataract ought to be left to a subsequent operation. The foreign body was found after some searching on the bottom of the vitreous and removed. Weight, 10 mgrs. The healing process was a regular one with very slight symptoms of irritation. A dissection of the capsular cataract on March 1, 1891, produced a round pupil in the center. Fundus clear; only fine opacities in vitreous. Vision—20/40 with +12.0D. Reads Snellen III with +15.0. This status has been the same up to date. As the other eye of the patient had been considerably injured by a previous accident (vision only 20/200), this one enabled him since to do his work and earn his living.

Case 8.—R. L., aged 28. Injury received six weeks previously in the country. A large piece of iron from a chisel had entered the eye. Large ciliary arc at cornea-scleral margin. Traumatic cataract. Iris dull and discolored. Chemosis. Swelling of the upper lid. The other eye injected; pronounced photophobia. As the patient was very anxious to have his eye saved, a last resort was made in spite of the symptoms of commencing sympathetic affection of the other eye. Scleral section. From the vitreous there was attracted at once a large piece of iron, necessitating enlargement of the wound in order to remove it. Weight 630 mgrs. There was some pus on its surface. On that account, and as the sympathetic symptoms rather increased, the shrunken eye was removed two days later. Under appropriate treatment the other eye recovered fully.

Case 9.—J. P., 52 years old. Piece of steel from a chisel entered the eye five days previously. Large irregular horizontal ciliary arc in cornea not fully closed as yet. Anterior chamber shallow. Pupil dilates only partially from atropin. Lens opaque. Place on laceration in anterior and posterior capsule recognizable; no reflex from fundus. The foreign body had most probably caused a considerable hemorrhage. I deemed it best in this case to proceed as in Case 7, especially as the corneal wound had not united fully. I, therefore, reopened and enlarged it, removed the opaque lens masses, and entered with the magnet through the pupil. In spite of long searching the foreign body could not be found. The patient disappeared a few days afterwards.

Case 10.—J. D., 14 years old. A piece of steel from a plate, crushed by a large hammer, struck the right eye. Seen immediately after the injury. Corneal ciliary arc in outer lower quadrant. Triangular wound in iris, which is slightly adherent to the ciliary. After atropinization, wound in anterior and posterior lens capsule visible. Ophthalmoscope reveals at the bottom of the vitreous an opacity with metallic reflex. Fundus otherwise clear. Operation three hours after injury in narcosis. Scleral section between inferior and external rectus. The click on touching the foreign body was heard twice, but it followed the third introduction only, having probably been firmly sticking in the sclera with its very sharp end. Weight 10 mgrs. Loss of one drop of vitreous. Conjunctival suture. Healing process normal. Traumatic cataract left to absorption. Dissection August, 1892. Vitreous considerably cloudy, especially in lower portion, and most probably retinal and choroidal atrophy. Counts fingers at 1½ meter distance. Status about the same now. It is doubtful if this moderate amount of vision will not become lost in the future.

The eight cases of extraction from the vitreous give the following results:

Two, good ones; 1, moderate one; 1, preservation of the eyeball; 4, failures.

The most extensive experience on this subject is possessed by Hirschberg, who reported (Graefes Archives, 1890) a series of 100 consecutive cases from 1879-90. Among them in forty-one, the foreign body was situated in the vitreous chamber and his results were:

Four, good ones; 3, moderate ones; 6, preservations of the eyeball; 28, failures.

His failures were in a large percentage of the cases due to septic infection already existing at the time of the operation.

Another large collection of cases has been reported by Mayweg (Archives of Ophthal., xxiii, p. 278). In fifty out of sixty-six the seat was in the vitreous chamber. His results were:

Nine, good ones; 7, moderate ones; 6, preservations of the eyeball; 22, failures.

In six the final result unknown. From the literature at my command, I could collect up to 1892 258 cases, including the above-mentioned series. The results of these were:

Fifty-eight, good ones; 40, moderate ones; 37, preservations of the eyeball; 123, failures.

The pronounced difference between these statistical results and those of Hirschberg is striking, but easily to be accounted for. These cases have been reported by numerous different authors, one or a few at the time and many of them beyond doubt too early. Furthermore, good results are published, as in surgery generally, failures passed over in silence. Therefore but little value can be attached to such collected statistics, and in my opinion only a larger number by one operator, or series of such, can form the proper basis to guide us. If the results so far have not been brilliant they have nevertheless been encouraging and they will undoubtedly become better with our increased experience.

Dr. J. L. THOMPSON—The first paper was a very valuable one on the use of the electro-magnet for the purpose of extracting foreign bodies from the vitreous. As to the second one, concerning quiescent bodies, we should like to have heard the last of that paper; without that we can say very little about it. Patients should be repeatedly warned by their physicians as to the danger of these foreign bodies. Tell them of the danger of the foreign body setting up inflammation many years afterwards. In such cases I have always given Solon's advice to Crotus: "Count no man happy until he is dead." There are some physicians who let the poor creatures go on with the injuries telling them: "Well, there is not much danger," until the patient goes on and loses the other eye. If the doctor had told him of the danger he would have been more practical and saved his eye.

Dr. BAKER—I had the pleasure in 1882 of spending some months with Prof. Hirschberg in Berlin and seeing him make several attempts at extraction of foreign bodies from the eyeball with an electro-magnet. On my return home in 1883 I had a magnet made, an improvement on his, in that it would lift five or six pounds while his would lift only ten or fifteen ounces. We have in Cleveland, as in all manufacturing centers, a number of penetrating wounds of the eyeball. It is always a difficult problem to know how to treat these cases, and the electro-magnet has been of much value to me in making a diagnosis. In a few cases it has proved of great service in the removal of fragments of iron or steel from the interior of the eyeball.

I recall one case referred to me by the late Dr. Weed in which he supposed the injury was only conjunctival and put a stitch in it; there was hemorrhage in the anterior chamber which obstructed the view with the ophthalmoscope. As soon as I brought the electro-magnet near the eyeball I knew there was a foreign body in it by the way in which the ball followed the magnet, and the pain complained of by the patient. I opened the wound and by the aid of the magnet soon found and removed the piece of steel, which was about

the size of my little finger nail. But it is still carrying the eye without any vision, but it looks as well as before. In another case I could see a piece of something that was larger than a pin head, very distinctly in the center of the vitreous. I made an opening in the chamber opposite and inserted my magnet repeatedly. I could hear the crack of the instrument against the foreign body but it would not come out. I kept this up for a long time but could not get it. After consulting with the patient we decided the eye must come out. I enucleated the eye and upon opening it took the magnet and passed it in contact with the foreign body but could not extricate it. I could lift the entire eyeball with this piece of steel adhering to the magnet, and yet it would not separate from the vitreous. The inflammatory capsule held this piece of steel there. I could have permitted that foreign body to remain without harm. I had another case not very long ago who had a piece of steel in his eye eight years; after that long time of quiescence it set up sympathetic inflammation and caused the loss of the fellow eye. I do not like the term, "quiescent foreign bodies in the eye." I do not think it best to convey the idea to the mind of the general practitioner that he can safely leave these foreign bodies in the eye. It might do if we could have them under our own control, but it is not well for us to let patients go from under our care with these foreign bodies in their eyes.

Dr. MUNN—I had occasion to present a paper last year on the subject of sympathetic troubles and how to deal with them. In reference to the first paper I will say that my experience with the electro-magnet has not been satisfactory. I have tried it in a few instances and have always failed to save the eye. The foreign body is usually tangled up in the fibers of the vitreous. I have had two or three typical cases and in each have failed and had to remove the eye afterwards. In reference to quiescent bodies in the eye, I think it is a very dangerous thing to leave them in position. Of course, we know that injuries in uveal tract are most liable to give rise to sympathetic trouble, but even in the vitreous humor there is danger of sympathetic trouble following if the foreign body can not be removed from the eye. I have seen a number of cases where foreign bodies have been carried a number of years and then have sympathetic inflammation set up in the other eye. I treated an eye with a piece of glass in it that had been carried for ten years. The piece of glass measured more than half an inch and had very sharp edges; sharp enough to cut. It had cut transversely through the cornea into the sclera about four millimeters on either side. It was evidently in the ciliary body, yet it was carried ten years without the slightest trouble. However, I advised the removal of the eye because the patient was blind and as a safeguard. On opening the eye I found the piece of glass. As Dr. Thompson has said, the patient was better without the eye, in his judgment, than to run the risk of carrying it.

Dr. JACKSON—The case reported by Dr. Baker in this discussion brings out a feature I do not remember to have seen mentioned, as to the use of the magnet in extracting foreign bodies from the vitreous. A foreign body can be dragged through the vitreous with very great difficulty or not at all by the magnet, unless you drag it through the wound of entrance. In one case I saw the patient thirty-six hours after the foreign body quite a small particle of steel entered the eye. The wound of entrance being small and the foreign body lodged on the other side of the eye a wound was made at the outer side of the vitreous chamber. Inserting the magnet, which was working well, it was tried repeatedly to drag the body out. The instrument would come in contact with the foreign body but it was impossible to dislodge it. So in Dr. Baker's case he tells me he had

made a new wound of entrance through which he introduced the magnet, and not through the wound made by the foreign body. This perhaps has been more frequently the cause of failure than has been noted. I think it much safer to have the foreign body out of the eye, if possible, but the large majority of these cases that do well after the magnet extraction are probably cases which might have done well had the foreign body remained in the eye.

DR. ALLPORT.—In regard to the use of the electro-magnet my experience has been rather unfortunate. I have upon several occasions extracted foreign bodies from the interior of the globe by the use of the magnet, but have subsequently lost the eye. The intra-ocular manipulation of the instrument has seemed to be more than the eye could endure. I would not, however, condemn the use of the magnet. Good results are reported and I may have been unskillful in the operation. It should certainly be used in superficial lodgment of foreign bodies that are beyond reach by other methods. But I should have to be absolutely *sure* of the presence of a foreign body inside the eye-ball to make any more experimental intra-ocular searchings with an electro-magnet.

In regard to quiescent foreign bodies in the eye I feel convinced that there is no safety while a foreign body is in the eye, and that if its extraction is impossible the eye should be removed. There are eyes that carry foreign bodies for years and thus produce a loss of both eyes. It is not conservative practice to allow patients to take such chances. These patients are usually laboring people of a low order of intelligence, and are apt to wander from one part of the country to the other. A sympathetic inflammation is liable to occur at any time under the most adverse circumstances as to skilled surgical attendance, etc. The loss of one or both eyes will be the probable result. We should do our duty and advise the enucleation of an eye, when we are sure of the presence of a foreign body before the patient passes from under our observation. In this connection let me advise some concerted action with regard to enforcing legislation calculated to prohibit the manufacture and sale of toy guns and pistols. In the month of June I was compelled to remove no less than three eyes from children who had been playing with these mischievous playthings. During the same month a medical friend of mine in Winona, Minn., was forced to mourn the loss of a young son, killed while playing with one of these dangerous instruments. If our wise legislators could drop for a time the discussion of such burning subjects as the smoking of cigarettes, the draping of nude statues, the covering of similar pictures, and the wearing of hoopskirts, and direct their attention to the advisability of permitting the manufacture and sale of toy guns and pistols, they would fill a longfelt want.

DR. FROTHINGHAM—I wish to discuss briefly two points that have been presented. The first is a statement that has been made by a previous speaker, that if a foreign body has entered the eye and we can not remove it we should enucleate the eye at once without regard to other conditions. I do not think experience warrants so "hard and fast" a rule as that. While in the great majority of cases enucleation will be necessary sooner or later, we should not decide the question of enucleation alone upon the fact that a foreign body is lodged within the eye, but upon the amount of injury and the reaction that follows; that is, upon the symptoms of an inflammatory nature in the injured eye that indicate danger to the other eye through sympathy. We all know that foreign bodies may remain in the eye for years without causing any feeling of discomfort or endangering the other eye. I once had a patient, an aged gentleman, who suffered from senile cataract. Many years before, while he

was a young man, he had a piece of steel enter the eye and lodge in the upper portion of the iris, where it had become encysted, and after a brief period of irritation had never troubled him in the least, and the vision had remained perfect until the senile cataract commenced to form. As the cataract was mature in this eye I operated, and in removing the usual section of the iris I removed the foreign body also. There are many instances where foreign bodies have remained in the deeper structures for many years without producing any symptoms that indicate enucleation of the injured eye. I had a patient a young man, suffering with pain in a blind eye, and sympathetic irritation of the other. The painful eye had been blind from childhood, but until a short time before consulting me it had caused him no discomfort. There was an injury of the iris, an absence of the lens, and a small scar of the cornea which indicated that a foreign body had penetrated the eye long before. He was then twenty-six years of age and said he had never received any injury of the kind. The eye was enucleated and a small piece of steel was found lodged upon the inner surface of the sclerotic. The patient afterwards recalled the fact that when a small boy, about six years of age, he was watching some men while they were drilling a stone, and that something struck him in the eye causing pain. This was a case where a foreign body had penetrated the eye, and yet, not until about twenty years afterward did it give rise to symptoms that called for its enucleation. This patient made a perfect recovery. Now there are a sufficient number of similar cases on record to forbid our acceptance of a rule that we should enucleate an eye at once if a foreign body has entered it, and we can not remove that body. If all symptoms of irritation speedily subside and there is no recurrence of pain or feeling of discomfort in the injured eye and the other is unaffected in any way we are justified in waiting, and under certain circumstances should wait until symptoms of pain and irritation recur in the injured eye and indicate danger to the other through sympathy. We should never allow a patient to go without warning, and should fully impress him with the danger of delay after symptoms of irritation recur in the injured eye, and in all cases where the recovery from the effect of the injury is not steady, and of short duration, we should enucleate.

I remember a case something like this one reported by Dr. Baker; the patient, a man of intelligence, had a small bit of steel penetrate his eye a few months before I saw him. The vision of the eye was not greatly impaired and there was on first examination but little indication of irritation or danger to the other eye, and I thought the patient was perhaps unduly alarmed; I hesitated to sacrifice an eye that possessed so good vision until thoroughly satisfied that it was necessary. Upon ophthalmoscopic examination the position of the foreign body could be plainly made out in the posterior portion of the vitreous humor, where it seemed suspended and surrounded by a thin film of semi-transparent tissue. I kept the patient under observation in the hospital, and finding that there were well marked symptoms of irritation at times which prevented his use of the other eye I decided to make an attempt to remove the foreign body, and failing in this to enucleate the eye. Having the patient's consent, I had him put under the influence of an anesthetic, and making the usual incision tried with a powerful magnet to extract the foreign body but without success. I then enucleated the eye which I opened; with the foreign body plainly in view and the magnet brought as close as could be I was unable to move it, although there seemed but a slight change in the vitreous surrounding the metal.

DR. LEVISON—I do not think there is anything more in

keeping with conservative ophthalmology than to enucleate the eyeball if any sympathetic irritation is present. A few days ago at my home in Denver on the day I was preparing to start for Milwaukee, a gentleman came to my office who had an injured eye. The ocular injection was very great and inflammatory action had gone to a considerable extent. The well eye I noticed, on examination, was wanting quite a little in power to accommodate. He said to me: "I came to get some medicine for my eye." I examined it carefully and found that it had been caused by the introduction of a foreign body. I told him he was running a considerable risk in allowing the affected eye to remain in its orbit and assured him that he had a sympathetic irritation in the well eye, which was likely to produce total blindness unless attended to at once. The affected eye looked phthisical, was minus tension and the vision was entirely gone. I said: "I will enucleate the eye for you, if you want it done, otherwise I will do nothing." He went away but soon returned and informed me that he would take my advice and have the operation performed. On opening it I found the remains of a foreign body.

About three years ago lady came to my office and said: "Doctor, I have come to get something to allay this inflammation in my eye." It had never given her such trouble before. It was brought about by the introduction of a small piece of thorn having pierced the ciliary body. I told her I would enucleate the eye by all means, as she was beginning also to have sympathetic trouble in the well eye, and that I could not be honest in advising her to try to hold on to the injured eye longer, as it would be running a risk that I would not carry for a thousand dollars a day. She refused to abide by my advice and went away and the sequelae will tell the result; in three months she returned, and I found that the injured eye had recovered, to a great extent, from the introduction of the foreign body, but on examining the other eye, alas! I found it too was in total darkness. Had I advised this woman at her first visit to me to have pursued the course she did, my conscience would haunt me to this very hour for not doing my duty. I do not say to do a wholesale enucleation for every foreign body—far from this; if sympathetic inflammation has manifested its presence I never fail to advise enucleation, and I have got the first case to regret for having taken such a course. I do not think we act wisely by attempting to carry these risks. This case is only one of a dozen or more that has come under my own observation with like results.

Dr. Horz—called attention to the fact that prognostically it made a vast difference whether the foreign body in the eyeball was lodged in the vitreous, or in the lens, or in the iris. General statements therefore on foreign bodies in the eye without mentioning the location must be misleading; for instance, when a gentleman said it was his rule to take any eye out in which he found a foreign body, he certainly did not wish us to believe he would enucleate eyes having a foreign body in the iris or lens; for these foreign bodies may be either left in situ or can successfully be removed and the eyeball saved. But conservative treatment can not be recommended for foreign bodies in the vitreous. The experience of all oculists, at all times, has been that foreign bodies in the vitreous are a prolific source of sympathetic inflammation. Such eyes are a constant menace to their fellows and should be removed; for we have no right to jeopardize the sight of thousands of eyes by a conservative treatment, because in some rare exceptions it has proved satisfactory. We must not be guided in our actions by what our experience of every day shows to be the usual course with such patients.

Prof. Zehendor (by invitation of the chairman) called attention to the experiments of Kries and Haab with electro-magnets of unequal strength for the extraction of iron

and steel from the eye without entering the eyeball, but by magnetic traction through the tunics. He has observed two cases operated on in this manner by Dr. Schlessner of Munich. In both cases the extraction of the iron piece succeeded very well and quite easily, but in one of these cases the piece was so big, that in spite of the extraction the eye was destroyed. He also related an instance in his experience in which he observed at the time the entrance of a foreign body into the interior of the eye in a boy, which was followed by retinal detachment and atrophy of that eyeball, but had not caused any sympathetic trouble in the fellow eye up to the time of his death sixteen years later.

THE ACTION AND SAFETY OF CHLOROFORM.

Being an abstract of a report to Surgeon Lieut.-Col. Edward Lawrie and the Government of His Highness, the Nizam of Hyderabad, India.

By H. A. HARE, M.D.

PROFESSOR OF THE PRACTICE AND MATERIA MEDICA, PETERSON MEDICAL COLLEGE, PHILADELPHIA.

AND E. Q. THORNTON, M.D.

DEMONSTRATOR OF THE CLINICAL.

To any one who endeavors to view the subject of chloroform anesthesia in an entirely impartial light, two objects raise themselves so high above all others that they form the peaks about which the smaller questions must cluster. The first object on which the judicial eye rests is the firm belief of many clinicians that chloroform may cause sudden cardiac death; the second object to be seen is the statement of the Hyderabad Chloroform Commissions that death from chloroform is never due to cardiac failure. In the support of the first belief we have not only wide clinical observation but also the experimental evidences of a number of investigations. In support of the second statement we have an array of experimental study, not equaled by any other research extant, associated with an enormous number of negative observations on man. Negative observations, because Lawrie alone in 25,000 cases has never had a death.

The controversy concerning the action of chloroform upon the animal organism has been waged so incessantly for many years, and has led to such extraordinary efforts for its elucidation and final decision that any one who attempts to take part finds himself swamped by the number of statements and opinions which he is forced to regard. We have, therefore, approached this research feeling it was no ordinary task, and that a path already so well traveled must be gone over with the utmost care if anything new or of value was to be discovered.

In March, 1892, Surgeon Lieut.-Col. Lawrie, whose interest in this subject is recognized by the medical profession the world over, wrote to one of us (Hare) asking that another chloroform research be instituted for which the Government of His Highness the Nizam of Hyderabad would pay. The express object of the research was the reconciliation of at least some of the contradictory conclusions reached by various experimenters during the past few years.

From the immense number of observations in regard to the action of chloroform in the laboratory and in the operating room it is evident that sufficient data are at hand to give us material to reach positive conclusions, and that the contradictory results hitherto obtained must have been reached by misinterpretation and error in experimental method, tintured perhaps by opinions formed previous to

the completion of a line of study. There are certain facts in regard to chloroform which few will deny, the chief of which are that it has the advantage of rapid action without disagreeable preliminary or subsequent symptoms, its bulk is small and its odor agreeable but, more important than all, it is much more dangerous than ether.

Though the Hyderabad Commission in their preliminary conclusions (page 30, paragraph 43) assert that ether is as dangerous as chloroform if given sufficiently to produce true anesthesia, we believe that the safety of ether is so universally recognized that this conclusion of the Commission can only be excused by the remembrance that ether has probably been used as little by those who wrote this paragraph as chloroform is used in many parts of America. This possibility is made a probability when we read that "if surgeons choose to be content with a condition of semi-anesthesia, it can no doubt be produced with perfect safety, though with discomfort to the patient, by ether held rather closely over the mouth. Such a condition of imperfect anesthesia would never be accepted by any surgeon accustomed to operated under chloroform." That this statement shows, to put it mildly, that the writer knows not whereof he speaks is proved by the universal employment of ether by hundreds of the best surgeons the world over in preference to chloroform. Further than this, medical literature contains so many statistical papers showing the small percentage of deaths from ether, compared to chloroform, that this point need not be discussed.

There are certain other points in regard to the action of chloroform which may be put aside as settled and therefore not needing further study, being generally received as beyond criticism, and we have made no experiments looking to their reproduction but have devoted our efforts solely to the question over which discussion still proceeds. Thus, all investigators concur in the statement that chloroform even in ordinary therapeutic quantity, acts as a powerful and constant depressant to arterial pressure. This conclusion has been reached by Bowditch, Minot and Coats, H. C. Wood and H. A. Hare, Gaskell and Shore, the Hyderabad Commission Nos. 1 and 2 and by every experiment in the research now carried out which forms this report. There is no evidence to the contrary and practically it has never been denied. Gaskell and Shore state, however, that chloroform may cause anesthesia without lowering blood pressure and that chloroform causes primarily a rise of pressure. They also believe that the chief cause in the fall of arterial pressure is cardiac and not vasomotor depression. The rise we have never seen except from struggles, and we have never been able to produce anesthesia without lowering the blood pressure, even when the drug was used in the smallest quantity capable of causing anesthesia and given as slowly as possible. We agree with the statement of the Hyderabad Commission that a fall of blood pressure always occurs when chloroform anesthesia is produced.

We are also forced, as the result of our studies, to differ entirely with Gaskell and Shore in their statement that the fall of arterial pressure is due primarily to a weakening of the heart's action and not to paralysis (depression?) of the vasomotor nerves. We believe that both factors cause the fall, but that the dominant factor is vasomotor depression because

as will be seen in several of our tracings the pulse waves were quite strong though the blood pressure, through vasomotor relaxation, was absolutely to the abscissa line and we agree with Lawrie that no conclusions as to the action of chloroform when inhaled can be drawn from the injection experiments of Gaskell and Shore into the arteries. One of our reasons for this belief is the entire difference in result. Another reason is that any powerful drug injected into the brain will cause a rise of blood pressure. Even nitrite of amyl, the prince of vasomotor paralyzants, will do this. (See Gaskell and Shore 17, paragraph 68). We also believe that results obtained by such interesting methods of experimentation as those employed by Gaskell and Shore are not capable of giving positively reliable information, as the conditions are so utterly at variance with those in which chloroform is given to man and, further than this, their methods are such as to give room for fallacious results which can not be excluded by the greatest caution on the part of experimenters experienced as they are.

Secondly, it is not denied by any one, that we know of, that chloroform exerts a powerful, depressant, paralyzant action on the respiratory center. This is agreed to by clinicians and by every one who has experimentally studied the action of the drug on the lower animals.

Thirdly, it is universally conceded that chloroform is a lethal agent of great power when brought in direct contact with highly vitalized tissues.

Aside from these facts there are a number of others in which we find ourselves strictly in accord with the conclusions of the first and second Hyderabad Commissions.

We find when the drug is pushed that insensibility comes first, then respiratory failure and finally cardiac arrest in every case in the lower animals. In other words, that cardiac arrest never ensues primarily from inhalation of chloroform.¹

SUMMARY.

From a careful study of the experiments so far reported, from studies made by one of us two years ago with H. C. Wood, and finally from this careful series of experiments we believe that the subject can be settled by the acceptance of both views in a modified form, or in other words that there is no real antagonism in the beliefs that chloroform kills by depression of the respiration or paralysis of the heart. We very positively assert that chloroform practically always kills by failure of respiration when administered by inhalation, provided, and this provision is most important, that the heart of the anesthetized is healthy and has not been rendered functionally incompetent by fright or violent struggles or, again, by marked asphyxia. By a healthy heart we mean one which has not undergone true fatty degeneration or has not so severe a valvular lesion as to make the slightest variation in the even tenor of the circulation fatal.

As positively as we assert that chloroform kills primarily by respiratory failure, so do we also assert that in excessive dose by inhalation it has a depressant effect on the circulation which is chiefly due to centric vasomotor depression with final depression

¹ Lack of space prevents the inclusion of three experimental records. They can be found in the issue of the Therapeutic Gazette for Oct. 15, 1902.

of the cardiac muscle itself. Depression of the cardiac muscle alone is never great enough to cause death when the chloroform is given by inhalation, but we believe that gradual asphyxia with the direct depression of the circulation may do much towards producing a fatal result, for vasomotor integrity is almost as necessary to life as an intact cardiac mechanism. This circulatory depression has been considered a safeguard because it was supposed to prevent chloroform going to the vital centers, but in reality it is no safeguard because profound circulatory depression is as great an evil as respiratory narcosis. That the circulatory depression may be dangerous is not only evident, but it is stated to be so by the Hyderabad Commission itself at the end of paragraph No. 8. This circulatory depression may be so profound that recovery is impossible, even with the most thorough artificial respiration, a fact stated by the second Hyderabad Commission in paragraph 25, which we quote in this paper. This emphasizes the fact that we can not afford to totally ignore the effect of chloroform on the circulation and we can not consider the patient in danger of circulatory failure *only* when the respiration ceases, but *as soon as it becomes abnormal*. On the other hand, we should remember that even if chloroform has been given properly, the arterial pressure may be so low as to give no pulse in the radial artery and yet the circulatory system be ready to respond at once when the drug is removed. If, therefore, the chloroform is properly administered is there danger of its circulatory effect in man? We think that it is just at this point that our research and every other research on animals fails and necessarily fails, to produce a positive reply. The variation in the action of a drug on a diseased individual from its effect on the normal one is notorious, and we have no right to dogmatically assert that there is absolutely no danger of a circulatory depression in man, even if we found no evidence of failure in dogs, because there may be many idiosyncrasies or variations through disease in the human being which may completely reverse the results of experiments on healthy animals.

In other words, supposing that the amount of depression from very full doses of chloroform equals 25 units this amounts to little in the normal heart, but if the heart be depressed 25 additional units by disease the depression of 50 units may be fatal, particularly if to this 50 is added 25 units more of depression through fright and cardiac engorgement through disordered respiration or struggling. That true depression of the heart muscle may take place under chloroform seems to us most undoubted and we think that the tracings in every research that we have seen support this view. There is always a decrease in cardiac power manifested by the decrease in the force of the individual pulse beat and this passes away only if chloroform is removed early enough. We also agree with McWilliams that from the very first inhalation of chloroform there is a constant tendency to cardiac dilatation.

We come finally to the all important questions:

1.—Is chloroform a safe anesthetic?

2.—Are we to watch the pulse or respiration during the use of the drug, and what are the signs in the respiratory function indicative of danger to the patient?

3.—What is the true cause of death from chloroform?

4.—Is death from chloroform possible if it is properly administered?

5.—Under what circumstances is the surgeon to use chloroform in preference to the less dangerous anesthetic, ether?

6.—What is the best way of administering chloroform?

To the first question the answer is yes, for the majority of cases, provided it is given by one who is skilled in its use and not only knows how to give it but to detect signs of danger. It is not as safe as ether at any time, other things being equal, and never safe in the hands of a tyro.

To the second question the answer is, watch the respiration, *because as soon as enough chloroform is used to unduly depress the respiration, the explanation will show some signs of abnormality, either in depth, shallowness or irregularity*. In other words, the very effect of the drug may be to cause such deep and rapid respirations that an excessive quantity of the drug is taken into the lungs and continues to be absorbed even after the inhaler is withdrawn.

As there is always a fall in pressure under chloroform it is difficult to feel the radial or temporal pulse and the respiratory center recognizes the degree of arterial depression, which its sister vasomotor center has permitted by finding that its blood supply is insufficient. As respiration fails first it should be watched first. Finally, it is only by watching the respiration that we can tell how much chloroform the patient is getting. We do not watch this function for danger alone but to tell us of the dose.

The answer to question three is that death is always due in healthy animals to respiratory failure accompanied by circulatory depression, which later may be severe enough to cause death even if artificial respiration is used skillfully. Death only occurs in the healthy animal when chloroform is given in excessive quantities.

Question four is impossible to answer for man from the basis of experimentation, as we can not produce identical diseased states in animals with those developed under various conditions in man. The physician having a case of heart disease should always advise the patient of the danger of any anesthetic and he should remember, whether it is wise to tell the patient or not, that anesthesia always means a step toward death even in the healthiest of men. In the event of a death under chloroform the physician is not to blame if he has taken proper preliminary precautions and given the chloroform properly.

Every one is agreed that the patient taking chloroform should have plenty of fresh air and in India we understand that to all intents and purposes patients are operated on in the open air, at least as compared to the closed rooms necessary in America and Europe. This free supply of air is important, whether we believe death to be imminent from cardiac or respiratory failure, but this supply of air matters little to the patient if he does not breathe freely nor does the dose of chloroform amount to aught if it is not drawn into the chest. The dose of chloroform is not the amount in the inhaler but the amount taken into the chest and finally the amount absorbed by the blood vessels. The rapidity and depth of respiratory movements is therefore, as Lawrie asserts, the entire key to the situation. We watch a windmill over a well to see if it is pumping into a reservoir a given quantity of water. If the

windmill works irregularly so that we know its pumping action is deranged we separate it from the pump until the wind blows steadily, in order that it may pump regularly. Similarly we withdraw chloroform, as Lawrie says, whenever respiration becomes disturbed in rhythm or when struggling disturbs it, because it is the first indication that the drug's action is uncertain and because there is no telling the dose which is absorbed. While watching the respiration will not warn us of a sudden cardiac arrest in fatty heart plus chloroform depression, neither will the pulse give us such warning and we are confident that the statement of the Hyderabad Commission that the *respiration should be watched is correct*, for we believe from a long series of observations that gradual cardiac failure never occurs without producing respiratory changes from the very first. In other words, we do not believe that in a healthy heart chloroform can cause serious disorder without as a result of beginning disorder disturbing respiration and, second, that in a healthy heart a quantity of chloroform sufficient to disorder it will by its direct action disorder the respiration. If, as an extra precaution, one assistant watches the pulse while the other watches the respiration, very well; for though the respiration is the more important function the man watching the pulse might discover an irregularity which the anesthetizer may not see reproduced in the respiratory action, but as divided attention generally means a slighting of both objects in view Lawrie is right in insisting on the pulse being let alone.

In answer to question five we have several points to offer: 1. Hot climates where ether is inapplicable and where a free circulation of air increases the safety of the patient; 2. Chloroform may be used whenever a large number of persons are to be rapidly anesthetized so that the surgeon may pass on to others and save a majority of lives, even if the drug endangers a few, as on the battlefield where only a small bulk of anesthetics can be carried; 3. Its employment is indicated in cases of Bright's disease requiring the surgeon's attention, owing to the fact that anesthesia may be obtained with so little chloroform that the kidneys are not irritated, whereas, ether, because of the large quantity necessarily used, would irritate these organs. Quantity for quantity, ether is, of course, the less irritating of the two; 4. In cases of aneurism, or great atheroma of the blood vessels, where the shock of an operation without anesthesia would be a greater danger than the use of the anesthetic, chloroform is to be employed, since the greater struggles caused by ether and the stimulating effect which it has on the circulation and blood pressure might cause vascular rupture; 5. In children or adults who already have bronchitis, or who are known to bear ether badly or, in other words, have an idiosyncrasy to that drug, chloroform may be employed; 6. Persons who struggle violently and who are robust and strong are in greater danger from the use of chloroform than the sickly and weak, probably because the struggles strain the heart and tend to dilate its walls.

The latest method of administration is by Lawrie's or Renarch's inhaler because these provide free circulation of air and do not distract the attention of the anesthetizer from the respiratory movement by complicated apparatus. Apparatus much like these, allowing a free amount of air, are the Hyderabad chloroform inhaler, or open-ended cone with

Krohne and Seseman's respiration indicator attachment. The Junker inhaler, even with its modifications, is too complicated and cumbersome and while less chloroform is wasted in administering the drug it must all be thrown out of the bottle afterwards. If used at all it should be used with the increased air supply and respiration indicator of Krohne and Seseman.

We agree so heartily with Lawrie's conclusions that we print them below:

1.—The chloroform should be given on absorbent cotton stitched in an open cone or cap. (A depression made through the opening in the inside flannel bag will answer as well.)

2.—To insure regular breathing, the patient lying down with everything loose about the neck, heart and abdomen, should be made to blow into the cone, held at a little distance from the face. The right distance throughout the inhalation is the nearest which does not cause struggling or choking or holding of the breath. Provided no choking or holding of the breath occurs, the cap should gradually be brought nearer to, and eventually may be held close over, the mouth and nose as insensibility deepens.

3.—The administrator's sole object while producing anesthesia is to keep the breathing regular. As long as the breathing is regular and the patient is not compelled to gasp in chloroform at an abnormal rate there is absolutely no danger whatever in pushing the anesthetic till full anesthesia is produced.

4.—Irregularity of the breathing is generally caused by insufficient air, which makes the patient struggle or choke or hold his breath. There is little or no tendency to either of those untoward events if sufficient air is given with the chloroform. If they do occur the cap must be removed, and the patient must be allowed to take a breath of fresh air before the administration is proceeded with.

5.—Full anesthesia is estimated by insensitiveness of the cornea. It is also indicated by stertorous breathing, or by complete relaxation of the muscles. Directly the cornea becomes insensitive, or the breathing becomes stertorous, the inhalation should be stopped. The breathing may become stertorous, while the cornea is still insensitive. The rule to stop the inhalation should, notwithstanding, be rigidly enforced and it will be found that the cornea always becomes insensitive within a few seconds afterwards. It is only necessary to add that the patient should be so dressed for an operation that his respiratory movements can be easily seen by the chloroformist. In the climate of India this is not difficult to manage, but it is rather more so in the climate of Europe; so that in this respect, and in this respect alone, the chloroformist in England and America is placed at a distinct disadvantage compared with the chloroformist in India.

NOTE.—Since writing this report two important papers upon this subject have appeared in the London *Lancet*. The one by Gaskell and Shore, in which they carried out a line of ingenious cross-circulation experiments, and from which they conclude that the fall in blood pressure seen under chloroform is due to cardiac rather than vasomotor depression; and another paper published by Lawrie, in the London *Lancet* for Feb. 11, 1893, in which he refutes the statements made by Gaskell and Shore, and details experiments which he believes combat those of the two investigators just named.

The concluding paragraph of Lawrie's latest contribution to the subject states the facts so clearly and is so in accord with what we have tried to set forth in our own report that we can not do better than quote the paragraph:

"The Hyderabad Commission's work proves that, while Syme's principles are right, there is no such thing as a safe method of chloroform administration. It is no longer a question of the superiority of the London method or of the Edinburgh method; absolute safety can be attained neither by watching the respiration nor the pulse for signs of danger—which are in either case proof of improper administration or of overdosing. Moreover, overdosing may take place whether the anæsthetic is given on lint or on a towel, or on a cap such as we use, or with Junker's or Skinner's or any other form of apparatus. The all-important point is that the breathing shall never be interfered with in any way. Safety under chloroform can unquestionably be insured, but it can only be so by attending to regular natural breathing; and, whatever method is employed, no one can deny that it is the bounden duty of the chloroformist to maintain natural breathing throughout the whole period of administration. To maintain natural breathing requires careful training and considerable experience, but if those conditions be fulfilled it is impossible to produce anything with chloroform but anæsthesia; and the Hyderabad Commission has shown that anæsthesia alone is entirely free from risk," provided the drug is not pushed too far and that the patient is in ordinary health. We would prefer to make the last sentence read: "Anæsthesia can be safely produced by chloroform."

SELECTIONS.

Summary of the Surgery of the Tendons.¹—WITH SIX ILLUSTRATIONS FROM LEVARS.—By JOHN B. HAMILTON, M.D., LL.D., Chicago.

The Surgery of the Tendons is the somewhat ambitious title laid down on the program as the title of my paper, but as time has not permitted me to review the whole subject in extenso, I will ask you to excuse my shortcomings, while I give you a condensed statement that will probably need no further condensation at the hands of your secretary. After all, I think most of the ideas that are new, or even presented in new form, can be stated in very few words.

I will pass over lightly the literature of the tendons, although that is very extensive, not only in medical literature, but in general literature. From the time Achilles' mother, Thetis, dipped him in the Styx, to make him immortal, by grasping tightly the tendons that have since borne his name, down to the middle ages when ham-stringing an enemy was a pleasant pastime of the bold Barons, the tendons have had considerable prominence.

In the surgery of modern war, where the wounds are made by bullets and rarely by bayonet or saber, the tendons are rarely wounded. For the very obvious reason that bullet wounds in battle are received on the body in exact proportion to the exposed area.

In civil life, the tendons are subject to dislocations more frequently than to wounds.

These accidents, though attended by few pronounced symptoms, need careful attention.

Contusions and punctured wounds need but scanty refer-

ence; owing to the lack of vascularity, contusion of a tendon is difficult to produce. Punctured wounds, when produced by any instrument causing laceration of the tendon fibers, are usually accompanied by retraction of the cut fibers and local necrosis of the connective tissue filaments, when made by a cutting instrument held parallel with the fibers, the wound closes with great rapidity, first by swelling of adjacent fibers from limited congestion; and second, by direct adhesion. The tendon sheath, however, made up as it is of loosely united connective tissue, is exceedingly liable to infection, and tenonitis, so called, almost invariably runs its course in the tendon sheath. Notwithstanding the fact that longitudinal wounds or separations of the tendons heal with rapidity, yet the resulting cicatrix impairs the efficiency of the tendon for a longer or shorter period, according to the area involved. Sometimes this impairment amounts to total suspension of the functions of the members; and the practical deduction from this lesson is, that in opening abscesses lying underneath a tendon, the incision should invariably be made at the side of the tendon, not through it. This practical advice, I believe, is not generally adhered to in the cases of finger abscess, but it should be. In abscesses of the fingers the original point of infection is usually the periosteum; the pus seeking exit in the line of least resistance usually projects from under the tendon on either side, and if the tension be not relieved at this time the adjacent bone participates in the inflammation, and it too becomes necrosed.

Fig. 1. Tendon Suture of LeFort.

Fig. 2. Tendon Suture of Wollast. After Levars.

Fig. 3. Tendon Suture of Levars.

It has been mentioned that the cicatrix impaired the functions of the tendon. Not only does this impairment occur but, owing to the feeble circulation of the tendon, the absorption of the redundant cicatricial tissue is slow, and sometimes the impairment is permanent. The sheath and the adjacent connective tissue being richer in blood vessels, not only accomplish repair sooner, but they more speedily remove the cicatrix.

Theories of repair of tendons after injuries have undergone the same successive changes as that of repair of wounds elsewhere. The theory of Hunter, that the elements of the blood were alone concerned in the repair of tendons, held sway until Bouvier in 1857 asserted that the tendon sheath by proliferation filled up the interspace between the ruptured ends. Denle, Robin, Adams, Paget, Brodhurst, adhered to the theory of repair by exudation and direct union of the

¹ Read at the Mitchell District Medical Society.

ruptured ends. Türeker, Donders, Virchow, Remak, Kölliker, Cornil and Ranvier have confirmed in the main the cellular theory of Bonvier by examination of cicatrices of tendons in man and animals and experimental tenotomies.

According to Krauss, who wrote a memoir on this subject in 1888, "the first alteration in the tendinous ends is like a degeneration; a shriveling at the center and a granular appearance of their protoplasm. But the principal modifications consist in a proliferation of the tendon cells, in which there is often observed the karyokinetic figures, and a corresponding enlargement of the fibrillar tissue. Afterwards the cells become round or angular and are prolonged from the fibrils, and the prolongations are found in the peri- or intra-muscular fascia."

Fig. 3. Suture by Anastomosis (Method of Schwartz). After Lejars.

We may conclude that repair is complete when the functions of the muscle are restored; but as the restoration of the tendon necessarily depends upon the length of the separation space, we must interfere if we desire to secure early union.

The question of suture of tendons is the one that most concerns the practitioner. Shall the ruptured tendon be sutured or left to nature?

Fig. 4. Method of Czerny. After Lejars.

Galen opposed the suturing of tendons, and so long as his authority remained undisputed, the interdiction prevented it. The credit of the change is given to Avicenna, and since his day surgeons have vied with each other in producing new forms of sutures, both in material and manner of application. My distinguished colleague, Professor Nicholas Senn, has been engaged for some time past in an exhaustive research of the medical literature of intestinal sutures, and the fruits of that research will soon appear in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. From that learned and instructive paper it will appear that it is almost impossible at this day to devise a new form of suture. This, however, only further corroborates the keen suggestion of Aristotle, "that probably all art and all wisdom had once been fully explored and again forgotten."

Fig. 5. Suture by anastomosis (Method of Tillaux and Duplay). After Lejars.

Not to take up your time with further historical allusions, I will only mention the sutures of LeFort, Wölfler, Lebentur, Tillaux, Duplay, Schwartz and Czerny.

The material most in favor at present is horse-hair, and chromized catgut. Subcutaneous wounds of the tendons do not require suture unless the distance between the ends

be very great, but all open wounds severing tendons require that the tendon be sutured. The difficulty which has led to so many forms of suture is the separation of the fibers by reason of their retraction; a complete ligature of the tendon could only result in strangulation necrosis of the ends. The drawings herewith from Lejars give you a fair idea of the different methods. Of these, perhaps the most ingenious is that of Tillaux and Duplay, which consists in suture of the peripheral end of a cut tendon in a slot cut in an adjacent tendon. Finally, we have the proceeding of Czerny, by which a splicing is effected by transplantation. Transplantation of tendon sections has been made by Glück, Georges Assaki and Fargin. Chassaignac as long ago as 1853 had united a tendon to the skin, in a case of section of the flexors of the thumb and index finger, and by the tension on the cutaneous cicatrix to which the tendon was united had good motion of the thumb and finger.

Where the separation is of long duration, both proximal and distal ends must be freshened.

LUXATIONS.—Dislocations of the tendons are quite common, the most common being the dislocation of the long head of the biceps, from the bicipital groove of the humerus. This accident is so thoroughly described in most works on dislocations, I will not dwell upon it here. The dislocation of the peroneal tendons from their groove at the external malleolus has escaped very much notice in the systematic works on surgery. I have seen two examples of this dislocation within the past year. Both were employees of the C., B. & Q. R. R., and both were switchmen. The accident may be recognized by pain, inability to turn the foot outwardly without pain, and the tendon may be seen and felt resting on the external surface of the malleolus. One of my patients acquired the habit of throwing the tendon out of its groove at will, the operation itself being painless. The attempt to walk while the tendon was in this abnormal position was very painful. He could reduce the dislocation easily by manipulation. The action seems to be produced while the weight of the body is thrown on the ball of the foot, the foot being extended and slightly rolled toward the inner border. Once produced its recurrence is common. The accident is also alleged to have occurred to horseback riders.

The reduction of dislocation of the peroneal tendon is easily effected, but the difficulty is to retain it in position. Fixation by the Martin's bandage, incision and suture have each their advocates, and Madyl of Vienna deepened the malleolar groove with a chisel; in my own cases, the men being on the hospital list of the railroad company, declined to submit to an operation. There is a strong probability that suturing the peroneal tendon to that of the flexor longus pollicis, which is adjacent, might prevent its return, but the operation of Prof. Albert seems to fully meet the indications.—*St. Louis Medical Mirror*, Sept., 1893.

Trional.—Koppers (*Lahen. Klin. Rund.*, 29, 30, 1893), observed the action of trional in twelve patients and arrived at the following conclusions: In most cases of simple insomnia, 15 grains sufficed to induce sleep within half an hour; 20 or 30 grains may be given if necessary, but with still larger doses the effect does not seem to increase proportionately. Where pain is present some, though not much, sleep results. Owing to the rapidity of its action trional is best taken at bedtime in some warm vehicle, such as milk or tea. The after-effects consisted only in slight heaviness in the morning, owing, apparently, to the direct action of the drug upon the cortex of the brain, and some slowing of the heart's action. If necessary, it also can be administered per rectum, the action thereby not being lessened.—*British Medical Journal*, Sept. 9, 1893.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE
PER ANNUM, IN ADVANCE \$7.00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the
Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any state or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate of statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 14, 1893.

EXTRA-UTERINE PREGNANCY.

Nothing in surgery is more typical of the advances which modern science has made than is the treatment of extra-uterine pregnancy. Although the axiom that death was due to hemorrhage and that the bleeding vessel must be secured was laid down over a century ago, it was a half century before the precept became practice and not until the present time, following the teaching of Mr. TAIT, has the practice received the sanction of the operators of the world. If there was nothing else of which he might be proud, the abdominal surgeon might well point to the life saving record in ectopic gestation.

Although the modern literature of the subject has assumed enormous proportions, beginning with the classical work of Dr. PARRY in 1876, there are still many points on which there is by no means a consensus of opinion in the profession. In the first place, there is a division as to the possibility of an absolute diagnosis previous to rupture. The disease is simulated by so many conditions, that it is unwise to lay down a train of symptoms which shall be taken as convincing evidence of the existence of an ectopic pregnancy. So closely does miliary disease of the ovary simulate ectopic pregnancy that skilled observers, men of wide experience, have been misled. The so-called "classical symptoms" of extra-uterine pregnancy are all here—the absence of one or more monthly periods, followed by a hemorrhage from the uterus, the morning sickness, the boggy tumor in the ovarian region—all may be present in tuberculosis of the ovary and may easily deceive the physician into thinking the case one of misplaced pregnancy. Again, the seeming extra-uterine pregnancy proves at the operating table to be a Fallopian tube filled with pus and causing the pain and hemorrhage that have given rise to the mistaken diagnosis. A pedunculated fibroma lying to one side of the uterus may present close resemblance to the graver trouble,

or a normal pregnancy in a thin-walled uterus may produce such symptoms as to render a positive diagnosis between the two conditions possible only after weeks of anxious waiting.

Men of the rare opportunities of study and the large experience of Mr. TAIT and Dr. JOSEPH PRICE confess that they have been misled repeatedly and are almost willing to say that a diagnosis prior to rupture is impossible.

Mr. TAIT, in his monograph on ectopic pregnancy and pelvic hematocoele, says:

"I have never but once been called upon to make an examination until the rupture had occurred, and in that case there was neither history or symptoms which enabled us to do more than determine that there was tubal occlusion, not, indeed until the rupture occurred and the abdomen was opened was a diagnosis possible. Under these circumstances I think I may be excused for maintaining a somewhat skeptical attitude concerning the correctness of the diagnoses of those gentlemen who speak so confidently of making certain diagnoses in cases of tubal pregnancy before the period of rupture, and who speak with equal confidence of curing the cases by a puncture, either simple, medicated or electrolytic."

Dr. PRICE is even more positive in his opinion as to the difficulty, if not impossibility, of diagnosis previous to rupture. In a recent paper he says:

"*Exceptionally, if ever, is the trouble recognized before rupture. The few cases recorded have all been by men with one experience, with very little knowledge of the murderous troubles found in the pelvis. A few surgeons, with an experience of nearly one hundred sections for ruptured tubal pregnancy, have never found one unruptured.*"

In the face of all the evidence on the subject it would seem that the diagnosis that is reported as made before rupture, is rather the result of a happy chance than the outcome of knowledge and weighing of symptoms on the part of the attendant.

After rupture the diagnosis becomes easy, though rupture has many times been mistaken for an abortion by the attendant physician. The sudden collapse with all the signs present of internal hemorrhage and the agonizing pelvic pain present a picture to the mind so vivid as to make mistake impossible. A pelvic examination and the finding there of a boggy mass to one side of the uterus would settle the case beyond a doubt and one feels inclined to ask if, in those cases that have been mistaken for abortion, a sufficiently thorough examination had been made or if the doctor merely took the woman's statement that she was aborting.

Rupture takes place either into the peritoneal cavity or between the folds of the broad ligament. If into the peritoneal cavity the wretched mother rapidly succumbs to the loss of blood and the peculiar and excessive shock that follows the accident. Rarely, it happens that the rupture takes place into the broad ligament and the fetus, developing in its new position, goes on to term and dies, condemning its

bearer to invalidism and all the horrors of abscesses breaking into bowel or bladder and discharging the bones of her unfortunate offspring.

It would seem as if common sense would point out the treatment. In any such hemorrhage from another part of the body, the physician would scarcely do his duty did he not seek out the bleeding vessel and secure it; yet we find men advocating anything rather than the surgical treatment. Puncture of the sac, injections into it of lethal substances, and electricity have all had their supporters. These agents find their use only previous to rupture and the uncertainty of diagnosis, and the fact that even in the hands of experts they have failed to save the patient from an operation are a sufficient answer to their claims.

That cases have recovered without operation is no reason that the surgeon should shirk his duty. The moment rupture occurs, the abdomen should be opened and the hemorrhage stopped by the removal of its cause. In no event should the case be allowed to go on in the hope that the patient, by some providential agency, may survive. The dangers of the hemorrhage, with the peritonitis and septicemia that follow the accident are too great to be set aside.

An important point in the surgical treatment is whether, in a ruptured tubal pregnancy of one side, the other side should also be removed to prevent the recurrence of the accident. In a paper on "Repeated Extra-uterine Pregnancy," published in the *JOURNAL* for Sept. 16, 1893, Dr. McKELWAY reports a case where the patient, after providentially escaping an untreated tubal pregnancy of one side was seized nine months later by a similar accident on the remaining side, from which she escaped only after a prompt operation and heroic measures. In discussing the case the author says: "My study of this and other cases leads me to the conclusion that both tubes and ovaries should be invariably removed in every case of ectopic gestation." In view of the fact that the causes of a pregnancy in one tube may be present in the other, is it right that the woman should be exposed to the chances of a repetition of the accident. The question is one of great importance. It is possible that the accident may never recur and there are many instances where the patient has subsequently had normal pregnancies and remained healthy. To offset this are the cases where the second ectopic pregnancy has followed a normal pregnancy. In the discussion which followed the paper, the conservative ground was taken that the other side should not be removed unless there was evidence of existing disease. Removal of the sound side adds slightly to the risks of the operation by increasing the shock and prolonging the operation; but, in a patient already at death's door and where safety depends on a short, dextrous operation, these considerations

weigh heavily. The question is one to which our operators with large experience should turn their attention, and it is for them to decide whether the chances of a presumably healthy tube being the site of a subsequent pregnancy are sufficiently great to call for the more severe procedure.

Another point is raised as to the treatment of the placenta in case the pregnancy is so far advanced as to render the removal of the entire sac impracticable or dangerous. Various plans of procedure have been devised. The sac has been stitched to the abdominal wound and drained; it has been sealed and left in situ to be absorbed—all with more or less good results. Sound surgical sense would teach that the safety of the patient lies in the complete removal of the sac wherever possible, and, with the agents at our command, heat and gauze packing, the hemorrhage can be controlled and the placenta removed in almost every instance with a prospect of safe recovery for the patient. Where it has grown so intimately to surrounding structures—often intestines and important viscera—it should be thoroughly cleansed by repeated washings with boiled pure water and hermetically sealed, in order that it may be digested and gradually absorbed with the least possible chance of septic decomposition.

A third question is whether, in case the patient survive a primary rupture the case shall be allowed to go on to viability of the child in order to save the life of the child. It is an obstetric maxim about which there is not the slightest cavil, that the mother's life is to be respected more than the child's, and it would seem that the added risk to the mother should weigh against the child's life and therefore the misplaced product of conception should be removed as early as it is discovered. Delays in this as in other matters are full of danger.

From the beginning to the end, extra-uterine pregnancy is full of danger. The sudden urgency of the accident, coming as it does without warning, makes it a matter of the greatest concern to the specialist and the general practitioner alike. In the majority of instances, the diagnosis must be made by the family physician, and the specialist comes in only to confirm the general practitioner's opinion and to perform the life saving operation.

"Tubal pregnancy is a grave, perilous trouble from the very instant of its inception, and from the instant of its first recognition there should be no suspension of the vigil over it. There is but one safe choice, and that is prompt removal when the accident is first recognized." Such are the words of a successful operator and they contain a truth that it were well to understand, and knowing to heed.

THE INTERNATIONAL PUBLIC HEALTH CONGRESS.

The meeting of the Public Health Congress this week constitutes one of the most interesting of the series of World's Fair International Medical Congresses. Interesting alike to the physician and the laity, the proceedings of the Health Congress are of value to all mankind. The cure of disease largely concerns the readers of the JOURNAL, but the prevention of disease appeals alike to all.

We are sure, therefore, that the address of PRESIDENT DUGIN which is printed exclusively in the JOURNAL, will be widely appreciated, not only on account of its intrinsic interest, but because the author as Chairman of the Board of Health of the city of Boston, for the past twenty years, has had exceptional advantages for the study and solution of most of the complicated questions of municipal sanitation, that are likely to interest health officers throughout the world.

The merging of the American Public Health Association with the International Congress of Public Health proved a wise measure, as the considerable number of papers on the program by foreign authors added much to the interest and success of the meeting.

That veteran of sanitary science, DR. JOHN H. RAUCH, was Chairman of the Committee of Arrangements, and he was ably seconded by DR. M. R. BREWER, the Secretary of the Committee.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

This organization has been in session during the past week in connection with the International Sanitary Congress, as will be seen elsewhere in the columns of the JOURNAL. It has arrived at its majority. This is its twenty-first annual meeting. The necessity for such an Association was felt immediately after the war by those who had been trained in the military service and had subsequently been called to act as health officials in a civil capacity. The war demonstrated the importance of preventive medicine. A fighting force has to be kept in fighting condition.

Textbooks on sanitary science were few, and the best of them were not adapted to the civic health officer. Each such health officer practically was acting independently. The necessity for bringing together, in one body, those interested in sanitary matters, for the purpose of inaugurating measures for the restriction and prevention of contagious diseases and for the diffusion of sanitary knowledge among the people, was so apparent that after several years of conference and correspondence the Association was formed in the fall of 1872.

The only attempt at organization prior to this was the quarantine convention, composed of representatives from the cities of Baltimore, Philadelphia, New York and Boston. DR. WILSON H. JEWELL of Phila-

delphia, was the leading spirit in this movement. This was at the time when quarantine was the only preventive measure used to combat foreign pestilence. This convention, after an existence of four or five years, had been extinct some time before the creation of the American Public Health Association. For several years the new Association required a great deal of labor and self sacrifice on the part of those who had inaugurated it to keep it in existence. The growth of the Association and the work it has accomplished prove the correctness of the views of its founders. Its membership has been augmented from year to year, until it now constitutes the largest and strongest sanitary body in the world, and embraces in territorial extent the United States, the Dominion of Canada and the republic of Mexico. Under the impetus given by its work, State and local boards of health and sanitary associations have been organized, sanitary publications increased, and hygienic knowledge widely diffused.

The terms of its membership are sufficiently broad to include all who are interested in public health questions. Its transactions not only contain reports of patient laboratory investigation, but the practical conclusions of those actively engaged in sanitary work.

Preventive medicine is necessarily and entirely disinterested and of the highest type of benevolence; and the American Public Health Association should have the cordial support of all who are interested in the well being of humanity.

THE INSPECTION OF MERCHANTABLE WATERS.

The vast number of places in our country where mineral and table waters are sold has made it a matter of solicitude whether or not they are what their label represents. It is not only distressing to be doubtful about the quality of the bottled waters, but it amounts almost to panic when we reflect that what purports to be Brother HART'S AROLLINARI may be a vile mixture, filtered from the Chicago River, or pumped from the nearest hydrant; and that even Wisconsin, Wauke-sa or Chippewa Spring water, to say nothing of the unnamed thousands, may also be either extremely stale, or altogether fraudulent in any market.

There is no question but advances in civilization will ultimately require protection of the people against fraud, but as yet we know of no municipal ordinance which requires the inspection of bottled waters. Not only is it an act of fraud to sell waters under a false label, but it is in effect criminal, when persons imagine they are receiving medicinal waters as prescribed by their physician.

There is a certain water in West Virginia of great value in gastritis. Now if any physician in any city knowing its virtues, should prescribe it, and the

patient obtain the product of the hydrant instead; no words could sufficiently characterize the fraud; and yet we are credibly informed that there exists in the city of Chicago, a factory where not only the labels, but the corks and bottles, may be procured in exact imitation of any known water. We doubt extremely whether Chicago is alone in this iniquity, and it is more than probable that a large percentage of the water sold in bottles is fraudulent.

The mere suspicion of fraud in the sale of these waters, is enough to cause many to turn to other beverages.

"If she be not fair to me,
What care I how fair she be."

If this be true of the bottled waters, what can we say of the waters delivered to customers by incorporated companies in bulk? The water *may* be good, but nobody can say so except the vendors themselves, for there is no qualified inspector.

The need for water inspection is therefore one of urgency, and we shall be pleased to record the date of passage of the first municipal ordinance for the prevention of fraud in the sale of potable and mineral waters.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

The annual meeting of the Mississippi Valley Medical Association was held at Indianapolis on October 4, 5 and 6, under the presidency of Dr. R. S. Sutton of Pittsburgh.

The attendance was less than at some meetings previously held, but it is easily accounted for by the recent financial stringency and the Pan-American Medical Congress. The proximity of the World's Fair at Chicago, and to a less extent the St. Louis Exposition served to attract members in those directions.

As usual, the American Medical Association members constituted about four-fifths of those attending, and their share in the scientific work was proportionate.

The papers were excellent, and we print in other pages an abstract of them.

The discussions were well sustained, animated and interesting. They would have been more voluminous but for lack of time;—the great number on the program allowed but limited time for discussion.

The high standard of the papers read at this meeting is a source of gratification to the well wishers of the Association.

A MEDICAL EDITOR'S RESIGNATION.

Dr. Cyrus Edson has resigned from the editor's chair of the *Doctor of Hygiene*, of New York. At least he is reported as saying that his name will not appear again as responsible for its management. The journal was formerly known as the *Doctor*, but soon after its change of name and the entry of Dr. Edson,

then the Sanitary Superintendent and later a Commissioner of the Health Department, the make-up of the paper became such as to attract attention. The names and portraits of the president and officers were published on the front cover, as if it were an official organ of the Board, and it purported to be "in the interests of American boards of health." Various schemes of a sanitary nature sought the columns of that paper, with the intention apparently of taking shelter under the roof of this bright project. A water-filter company at the head of which Dr. Edson's name figured, was among these. The imputation, however, that the position of the latter as a health official was liable to misuse for private gain, led him to withdraw from the company. There have been a great many resignations of late years in relation to the New York Board, but very little repose. The politicians have their grip on it, and use it to the utmost of their power.

ORGANIZATION A PROFESSIONAL NECESSITY.

The *Medical News* of Philadelphia, which has been making many pointed appeals for a greater and stronger union, in a recent and able editorial on the attitude of the lay press to the medical profession says:

"A Philadelphia newspaper lately made itself the agent of some patent medicine cure-all, and distributed thousands of bottles over its counter.

"There remains, of course, the humiliating confession that the existence of the newspaper doctor and of the newspaper debauch in quackery is indirectly and in large part the fault of the profession itself, dependent upon the fact that we are a non-organized profession, and that what organization we have is not used in the practical righting of medical abuses. Thus, again and perpetually, recurs the truth that every medical scandal and every aspect of our powerlessness resolves itself into our sins of disorganization, and of non-interest in practical matters and in preventive medicine. Out of a hundred thousand physicians in America hardly a hundredth part are active members of the American Medical Association, and the section meetings of "congresses" of physicians could almost always be held in an ordinary private sitting-room of a workman's cottage—so slim is the attendance. And when we do meet we discuss the symptoms and treatment of individual cases of illness, leaving out of consideration the production of disease, the prevention of it, and the domination of legislation, the newspapers, and the lay-world by the quack and the pill-vendor.

"How can we bring any influence to bear upon the newspapers if we present the spectacle of a disunited and factional lot of scoundrels and indifferentists? There are many of these newspapers who are simply ignorant and thoughtless as regards the disgrace of their advertising columns, and who could easily be shamed out of it if we were but united among ourselves, and would use our united strength for matters of practical reforms of medical abuse and preventive medicine. Organize, and use organization for the world's sake! is the command of professional honor and of benevolence."

HONORS TO PROF. POZZI.—The Chicago Gynecological Society, of which Dr. E. J. DOERING is President, gave a dinner to Prof. S. Pozzi, Professeur Aggrégé to the Faculty of Medicine and Surgeon to the Lourcine-Pascal Hospital of Paris, on Friday, October 6.

SOCIETY NEWS.

Mississippi Valley Medical Association.

Abstract of the Proceedings of the Nineteenth Annual Meeting held at Indianapolis, Ind., Oct. 7, 8 and 9, 1893.

FIRST DAY—GENERAL SESSION.

The Association met in Plymouth Church, and was called to order by the Chairman of the Committee of Arrangements, Dr. GEORGE J. COOK of Indianapolis.

Divine blessing was invoked by the Rev. Frederick E. Dewhurst.

Governor MATTHEWS was introduced and delivered an ADDRESS OF WELCOME.

The President, Dr. R. STANSBURY SUTTON of Pittsburg, was introduced and delivered the President's Address. He selected for his subject,

FIBROID TUMORS OF THE UTERUS.

After giving a definition of these tumors the author dwelt upon the etiology, which he said is still a mystery. They are more frequent in the black than in the white race. In both races they are more frequent in the body than in the neck of the uterus, and more frequently situated in the posterior than in the anterior wall. After the menopause is established these tumors generally disappear, unless they have undergone cystic degeneration. Bearing on this point Dr. Sutton reported an anomalous case. The patient was 43 years of age, she had never menstruated in her life, had never shown any physiological evidence of ovulation, had been twice married, was then a widow and childless. She had for ten years a large fibro-myoma of the uterus, which thus far gave no evidence of atrophy.

With regard to the pathology, the tumor always has its origin in the substance of the uterine wall or sub-peritoneal connective tissue.

The symptoms attending the presence of these tumors in various localities and stages of growth are widely different. However, the class of indications are patent as found in the vast majority of cases, and may be tabulated as follows: 1, vague pain in the pelvic region; 2, pain referred to the front or back of the leg; 3, irritability of the bladder or rectum; 4, uterine tenesmus; 5, menorrhagia or metrorrhagia; 6, dysmenorrhea; 7, profuse leucorrhoea; 8, serous discharge from the uterus.

The diagnosis of very small fibro-myomata, when many of the leading symptoms are absent, is considered extremely difficult. As far as the medical treatment is concerned, but little can be done for the relief of patients suffering from fibro-myomata, and nothing for those suffering from those tumors which have undergone cystic degeneration. Surgically, there are but two routes by which solid, uterine tumors can be removed, either through the vagina or by abdominal section. With the exception of small tumors with a well-defined pedicle, all sub-peritoneal fibro-myomata are reached only by section of the abdominal wall. Dr. Sutton in one case divided the posterior wall of the vagina and through this opening delivered the tumor.

SECTION ON GENERAL MEDICINE.

Dr. O. EVERTS of College Hill, Ohio, Chairman.

FORENSIC MEDICINE.

This paper was read by Dr. C. G. COMEYNS of Cincinnati. The author had come to the conclusion, from his experience, that there are but few lawyers sufficiently informed in medical science to conduct a case in the interests of truth and justice, especially the most important cases in medical jurisprudence. Every physician, as an expert witness, must have observed the embarrassment of lawyers in trying medical cases. They ask questions enough, but from their lack of medical experience they are incapable of thoroughly understanding the answers of a witness, so that the proper interpretation of them, bearing upon the history of a case at the bar, may be reached, and when endeavoring to give the court and jury clear views of the subject by additional questions, they often confuse the whole investigation. This disagreeable state of affairs is usually brought about by certain lawyers who have armed themselves by a superficial study of medical works for the occasion. Dr. COMEYNS believes that the high order of legal men will welcome well-trained men in medicine as coadjutors in the lofty work of establishing justice.

PROBLEMS OF PUBLIC INTEREST CONCERNING THE INSANE.

by Dr. ORPHEUS EVERTS of College Hill, Ohio. The author

said there are several problems of public interest involved in the present relations of society to the insane. Among the more important of these are questions of dependency and curability of the insane and the preventability of insanity. The author summarized his conclusions as follows:

1.—Intelligent provision for the insane implies provision for various classes, according to the capabilities of enjoyment and the exercise of variously impaired faculties.

2.—Public provision for whatever class of insane persons implies housing, clothing, food, sanitary and moral discipline, amusement and employment for such as are capable of being amused and employed, and medical treatment for the sick. The essential features of such provision are adaptability to the needs of each distinctive class.

3.—Great, expensive, architecturally imposing palaces, providing alike for all classes, however serviceable they may have been, ethetically considered, in times past, as they unquestionably were, are no longer necessary nor appropriate to the needs indicated. So long as the insane are comfortably housed, each class according to its condition, it is comparatively unimportant whether it be in large or small houses, cottages or palaces, connected or detached, in high or low buildings.

4.—It is important that the insane of all classes be well fed under careful supervision; but whether in small or large dining rooms, by groups or congregations, is of little consequence; that it should be a matter of convenience rather than of number.

5.—It is important that public institutions for the insane be well organized and administered.

6.—It is wise to retain in office capable men who have demonstrated their fitness by successful management of affairs, so long as their capabilities continue to be elastic.

CHOREA IN ITS RELATION TO RHEUMATISM.

This paper was contributed by Dr. L. N. LOVE of St. Louis. The author said that recently the pathology of this disease has been cleared up to a very considerable degree, so that now it is a definite affection and one especially incident to childhood. Dr. LOVE reported a case of chorea occurring in his practice with a marked history of rheumatism, it being one of ten cases observed and illustrative of this class. The cases did not occur successively. Between them other cases presented themselves *anecdotally* the rheumatic history, but four of the number occurred in rapid succession with as pronounced rheumatic history. Of the entire ten, seven were girls. Among the exciting causes of the disease are irritation in the nostrils and adenoid growths in the vault of the pharynx. Inasmuch as Kirkes, Tuckwell, Hughlings Jackson and Bastian support the embolic theory of the disease, and in consideration of the fact that chorea is so frequently associated with endocarditis, we should be on the alert to interrogate the heart when called to a case of chorea. As matters now stand, we have numerous exciting causes resulting in chorea.

CHOREA: ITS PATHOLOGY AND TREATMENT.

This paper was contributed by Dr. H. M. LASH of Indianapolis. So much uncertainty has existed regarding the pathology of chorea, that its treatment has been varied and widely different in its character and aim, amounting even to empiricism. Under all forms recovery has been recorded; but it is certainly interesting to note the variety of views which have been from time to time, and which are still held, in regard to this most peculiar disease. The author then gave the causes of chorea as laid down in the recent work on nervous diseases by Dr. Landon Carter Gray. He referred to the repeated experiments of Dr. H. C. Wood, who announced his conviction that the choreic movements had their origin in the spinal cord and were directly due to paralysis or depression of the inhibitory function of the cells of the spinal cord. Acting on the strength of this conviction, Dr. Wood sought for a remedy that would strengthen the proper function of these cells, and he found it in quinin.

Dr. Lash then reported a case of acute chorea in a boy 13 years of age. The choreic movements were constant, general and pronounced. It was agreed to try Dr. Wood's suggestion, and so the patient was put on full doses of quinin. Twenty grains a day, in four doses, were given him for three days, when he showed considerable improvement. The quinin was increased to 25 grains a day and given in that amount for three days more, when the patient again reported. There were no remaining symptoms of the chorea, and the quinin was gradually withdrawn. The patient has remained entirely free from the trouble ever since, and

without any future treatment of any kind. Another similar case was reported with a successful result.

DIPHTHERIA: ITS SPECIFIC DIAGNOSIS.

This was the title of a paper read by Dr. J. C. Culbertson of Cincinnati. The author said that this disease is of peculiar interest because of its singularity in being more treacherous and insidious in its manifestations than any other affection that is met with by the practitioner of medicine. The uncertainty of diagnosis had caused some excellent practitioners to adopt the pernicious habit of diagnosing and treating all cases of sore throat, whether simple or malignant, as if they were true diphtheria. True, the treatment designed for diphtheria may cure a tonsillitis, but inestimable harm may have been done in causing an unnecessary alarm on the part of the patient's family, and the disagreeable inconvenience that accompanies isolation of the patient and quarantining of the family, to be followed by the mockery of disinfection of non-infected apartments and perhaps destruction of clothing and furniture. On the other hand, a case of diphtheria, diagnosed as a simple tonsillitis, may be the cause of breaking up a school or producing an epidemic, with an indefinite amount of sickness and many deaths. A case was cited in point.

Dr. Culbertson then referred to the importance of utilizing the science of bacteriology and mentioned the plan adopted by the New York City Board of Health of having undertaken to provide laboratory facilities for all practitioners of medicine in that city free of charge.

A TREATMENT GIVING A LOW DEATH RATE IN CASES OF DIPHTHERIA IN HOSPITAL AND PRIVATE PRACTICE.

Dr. WILLIAM A. GALLOWAY of Xenia, Ohio, read this paper. The subject was treated from the standpoint of recent hospital practice, 234 cases with a death rate of 14 per cent, under favorable sanitary surroundings. The paper embraced reports from private practice of physicians who had given the treatment faithful trial during the past three years, who unhesitatingly commended its value and all were able to show a death rate below 10 per cent. The subject was divided into the *hygienic*, in which the most careful attention was paid to the isolation and surroundings of patients; the *constitutional* and *local topical* treatment, the latter being considered by the writer as secondary in importance. Under constitutional treatment, immediately the nature of the disease was suspected, the writer gave 1 grain of calomel for each year of the patient's age up to 18, repeating the dose in four to six hours, and met the action of the mercurial with copious hot water injections. This treatment was persisted in until the full action of the calomel on the liver and kidneys was obtained, relieving these two important excretory organs of the parietic condition caused by the absorption of the toxalbumin product of the Klebs-Loeffler bacillus. Improvement in the patient's appearance was immediate and the mercurials acted freely. The quantity of foul smelling grass-green dejecta resulting is astounding. There is no fear from salivation, as under the most heroic use of mercurials no symptom of salivation has been observed by the writer or his friends. Internally corrosive sublimate was given up to 1-80 of a grain, with full doses of tincture of chlorid of iron and alcohol hourly at night and during the day. Local topical treatment consisted of peroxid of hydrogen, one-quarter solution, for cleansing the throat, which was commended, while as an escharotic 12 grains of salicylic acid to 1 drachm of alcohol were used twice a day by the physician only. It proved of great value in the writer's hands. This escharotic is very powerful and should be used carefully if needed.

THE STUDY OF A FATAL CASE OF ESSENTIAL TACHYCARDIA.

This paper was contributed by Dr. JOHN C. SEXTON of Rushville, Indiana, in which he detailed the symptoms and clinical features of a case of essential tachycardia that died after thirty-five days illness. The attractive feature of the case was the response to manipulative efforts, electrical and other, by the Doctor, to produce stimulation of the pneumogastric nerve and thus to slow the heart. The paper then reviewed the ordinary symptoms of heart hurry as presented in the literature of the subject and some further remarks concerning the causation, symptomatology and treatment.

Papers were also read by Drs. R. E. Houghton of Midland, Texas; A. Ravogli of Cincinnati, and others.

The address on general medicine was delivered by Dr. JAMES I. HUBBARD of Richmond, Ind. His conclusions were:

1.—That there is a rapid progress being made in preventive medicine.

2.—That our present conception of the complicated organization of the human body is based on the theory that the Creator in the beginning endowed vitalized matter with a perpetual law of virtue of which man has been developed, step by step, from primitive protoplasm.

3.—That there is no longer dubiety in the proposition that the cell is the unit of vital activity, and that all living beings are a single cell or an organization of cells and cell products.

4.—That the influence of the mind on vital activities, normal and abnormal, is not recognized as it should be, and that there is a line of study that would, if properly pursued, dissolve the agnosticism that has in the past embarrassed a knowledge of the reciprocal relations of matter and mind.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY.

Dr. ARTHUR W. JOHNSTON of Cincinnati, Chairman.

The first paper in this section was read by Dr. REUBEN B. HALL of Cincinnati, entitled,

OVARIOTOMY IN THE AGED.

The author confined his remarks to patients who were 70 or more years of age. He said it was generally conceded as true that any operation upon the old did not promise as good results as the same operation would upon the young or patients in middle life. Especially was this true in reference to all abdominal operations necessitating a hard strain upon the system from shock, or from traumatism to vital organs during the operation, as we not infrequently have in the removal of large ovarian tumors. Dr. Hall maintains that the death rate is not greater than that which usually follows the same delayed class of operations on women between 40 and 50 years of age. He had had but three ovariectomies upon women above 70 years of age. In each of the first two cases the friends of the patients hesitated to have the operation made on account of the advanced age of the patients. In each of these the operation was deferred until the patient was in extremis.

Dr. Hall then detailed three interesting cases of ovariectomy performed on patients, aged respectively 70, 70 years and six months, and 72 years. Judging from the low mortality of the reported cases and from the work of the best known operators, the author is constrained to believe that ovariectomy in old women, if the kidneys are healthy, is as safe as in middle life.

THE VALUE OF A CLOSE OBSERVATION OF OTHER MEN'S WORK.

This paper was read by Dr. WILLIAM H. LINK of Petersburg, Ind. He said it is by the tireless energy of originality and the endless application of original methods to both the expected and the unexpected in surgery, that has thus far pushed our work and its underlying science toward perfection. By close and frequent observation, defects in technique and improper application of surgical measures may be noted and, having been recognized, may be avoided. There is no field in which object lesson teaching is so effective, so fruitful of valuable practical results as in gynecological surgery. The observer may not always know whether the operation he witnesses carries the patient on to recovery or the contrary; but, if a close observer, he is improving his own surgical judgment. He is studying, rejecting, or adopting methods and aphorisms as they impress his intelligence or his reason approves. By seeing work done under varying conditions and with different results we readily come to the conclusion that a private hospital is by no means necessary to successful work; that the pure air of a country or village home, or a clean room in a private residence in a city is as good a place for surgical work as the most painted and gilded hospital, and that no one need hesitate because his patient can not have the supposed advantages of some place specially set apart for the sick.

Dr. L. H. DENNING of Indianapolis, Ind., read a paper entitled

INTESTINAL OBSTRUCTION FOLLOWING ABDOMINAL SECTION.

Of the complications following abdominal section, few are more fatal than occlusion of the intestines. It may appear in a few hours after the section or not until several weeks have elapsed. In this paper the author dealt with only acute intestinal obstruction. The author is conscious of having met with but a single case in 130 abdominal sections, yet this case occurred two and a half weeks after what he had considered a very successful ovariectomy. The question of the administration of cathartics in cases of suspected or threatened occlusion of the intestines is one oftentimes most difficult to decide. Under such circumstances he is inclined to the belief that during the first week after sec-

tion cathartics are indicated, and he prefers to administer 1 grain doses of calomel every hour for a few times, then administer 2 drachm doses of epsom salts every two hours until an action is obtained, or it is demonstrated that a harmful effect is being produced. A distinct understanding of the pathological conditions possibly present must guide the operator in his search for the cause of the condition, and when found it should be dealt with in the shortest possible time consistent with the permanent cure of the patient.

THE PRESENT STATUS OF THE TREATMENT OF UTERINE FIBROIDS.

This paper was contributed by DR. NAXIER O. WELDER of Pittsburgh, and in the absence of the author, was read by DR. THOMAS E. EASTMAN of Indianapolis. For the sake of convenience the author divided the treatment into the symptomatic and the radical, and confined himself to those views which seem to be generally accepted by the leading and unbiased authorities of the present day. The principal symptoms produced by uterine fibroids requiring our attention are hemorrhage and pain. Hemorrhage is one of the most constant and dangerous complications, and is due to diseased and hypertrophied condition of the uterine mucosa and hyperplasia of its blood vessels (Wyder), or according to the later researches of Sembi, to a hypertrophy of the uterine muscles accompanying the growth of the myoma with a simultaneous hyperplasia of the blood vessels. The operations practiced for the radical cure of myomatous growths are vaginal enucleation, removal of the appendages, enucleation by laparotomy, and supra-pubic hysterectomy. The author then considered these operations at length.

THE ERECT POSTURE FOR GYNECOLOGICAL EXAMINATIONS.

This paper was contributed by DR. WILLIAM B. DEWEES of Salina, Kan., but was read by DR. JOHN C. SEXTON of Rushville, Ind.

Digital examination per vaginam with the patient in the erect posture affords one of the most positive means for diagnosis in gynecology. It is a well established fact that respiration, the various movements and attitudes of the body, as well as pathological conditions, change the conditions and environments of the viscera. Thus the importance of posturing the patient in making physical examinations in gynecic practice becomes evident, as most of the symptoms of diseases of the intra-pelvic organs are more marked and very many only manifested when the patient is standing; while certain conditions of descent, prolapse or displacement, may entirely disappear or change when the pressure or the superincumbent weight of the abdominal viscera is removed by the patient being placed in the dorsal, semiprone, genupectoral, or high pelvic positions, therefore the erect posture is of paramount importance as an aid in diagnosis in this field of labor. The author emphasized the advantage and necessity of digital examination in the erect posture, more particularly in examinations undertaken for a cure in women of 1, displacements of the uterus; 2, vesical and rectal disorders; 3, lack of perineal and vaginal support; 4, ovarian and tubal disorders; 5, abdominal and pelvic tumors; and 6, differentiation between abdominal tumors and pregnancy.

DR. H. O. PANTZER of Indianapolis, read a paper entitled,

TUBERCULOSIS OF THE PERITONEUM WITH REPORT OF CASES.

The author said that the prognosis and treatment of peritoneal tuberculosis have changed within the last decade. The accidental discovery of its curability by laparotomy has shifted its clinical relations. He then quoted the conclusions of Dr. J. Whitridge Williams, from the Johns Hopkins Hospital reports, 1892, on tuberculosis of the female generative organs. He reported a case of primary genital tuberculosis, giving rise to a tubercular peritonitis, and tubercular disease of the abdominal parietes. Case 2 was one of primary genital tuberculosis following childbed, sacculated ascites resembling an ovarian tumor. Laparotomy was performed and the patient recovered. Case 3 was one of genital tuberculosis complicated with a suppurative infection and pelvic peritonitis. Laparotomy was done, followed by recovery of the patient. This disease, from being regarded as a fatal and most intractable affection belonging to the domain of internal medicine, since its accession to the realm of surgery has come to be regarded as quite submissible. A mistaken diagnosis had repeatedly led to the opening of the abdominal cavity. Instead of an ovarian tumor, an enlarged gall bladder, a hydronephrosis, or some other legitimate object of surgical interest being found, tubercular disease of the peritoneum in some of its multiple forms presented itself. The abdomen was closed with-

out any attempt at treatment, or at least the pus fluid was evacuated. It was noted that these cases did better afterwards, and that some fully recovered. In 1884 King advocated laparotomy as a curative measure for peritoneal tuberculosis, and the operation has been done by other surgeons since.

TREATMENT OF DISEASES OF THE UTERINE APPENDAGES.

DR. WILLIAM H. HUMPHRIS of Cleveland, Ohio, read a paper on this subject, in which he said the frequency and importance of diseases of the appendages are recognized by all practitioners of medicine. The early recognition of the same is of unusual importance, as by instituting proper treatment at once we save a large percentage of them from a major operation and a prolonged convalescence. Simple inflammatory conditions of the tubes and ovaries, before extensive adhesions take place can be successfully treated by rest, boroglycerid, and iodine tampons, long continued hot water douches, thorough curettement of the uterus, followed by a course of galvanism. He had cured a few cases where the ovaries were prolapsed and somewhat adhered, by adding massage to the above treatment. But, as a rule, if the case has been neglected until pelvic peritonitis has occurred with its tendency to adhesions and recurrence, we will save many years of suffering, if not life itself, by advising removal of the appendages after a sufficient trial has been given to conservative treatment.

Frequently in the puerperal state we have a pelvic peritonitis arise without affecting the tubes, the inflammation spreading directly through the uterus; there is an exudate formed which rest and proper treatment will absorb and leave the appendages strong and healthy, so that later pregnancy takes place and the patient goes on to full term. In these cases, if suppurative occur, laparotomy should be advised. In tubercular salpingitis the question of removal will depend wholly upon the amount of general systemic infection. The author believes that nearly all suppurative diseases of the tubes and ovaries are due to gonorrhea, his experience leading to this belief. The doctor closed with a few words on the value of electricity in the treatment of inflammations of the uterus and appendages. He values this very highly, and in the catarrhal forms of endometritis in young girls and primiparae we can obtain a cure if sufficient time is given. He applies the positive pole intra-uterine, and the negative in the form of a broad electrode over the whole abdominal region, using a strength of from 20 to 50 milliamperes for five minutes every third day. It requires from fifteen to twenty applications to complete a cure.

XERODERMA PIGMENTOSUM.

DR. A. W. BRAYTON of Indianapolis, presented two cases of Kaposi's disease—xeroderma pigmentosum—occurring in the same family. The patients are girls, 2½ and 18 years old respectively. A brother died of the disease at 9 years of age. There are four brothers unaffected. All three were affected from the fifth month of infancy. Dr. Wm. S. Corlett of Cleveland, commented on the cases, of which but fifteen are known in the United States. The older girl is kept comfortable by scraping off the tumors upon the hands and face as they appear. A tumor the size of a hickory nut upon the eyelid Dr. Corlett advised to be removed by electrolysis. A lithograph and description of this case was published in the *Journal of Cutaneous and Venereal Diseases* for April, 1892. Dr. Brayton also presented a case of non-pigmented sarcoma of the face in a woman 28 years old. The lesions were on the right side of the face, and varied in size from one-eighth to an inch in diameter. The larger ones had been destroyed by electrolysis, but returned. The growths probably originated from an infantile nevus. The microscopic sections accompanying the case showed it to be small-celled sarcoma. The growths were painful, but not ulcerating, and there is so far no metastasis. Dr. A. Ravogli saw and commented upon this case.

Another case also examined by Dr. Wm. S. Corlett was of idiopathic pigmented sarcoma cutis of twenty-five years' standing in the person of a physician 75 years of age. The growth began below the external malleolus of the left foot. After ten years the whole left leg was involved, and five years later the right leg, the left arm and external margin of right ear. The tumors vary from the size of a wheat grain to that of a silver dollar and are little elevated above the skin. They undergo involution after four or five years, leaving well marked cicatrices. This case was also commented on by Dr. Corlett. It belongs to the extremely rare growth—multiple pigmented sarcoma cutis of Kaposi described by Dr. J. A. Fordyce in the *Journal of Cutaneous*

and *Fungal Diseases*, January, 1891. Dr. W. A. Hardaway reports a case which underwent complete involution after sixteen years, leaving merely an atrophic condition of the skin. In the present case the tumors, at first soft, become fibrous and disappear, leaving scars. Upon the legs nearly the entire area is involved. The health is good. The microscope confirms the diagnosis. Taylor reports a similar case of this rare affection.

A case of lupus mutilans (Hutchinson) in a colored girl 8 years old, existing from infancy, was also shown. The entire left arm was scarred by the disease; one finger was diseased to the bone; the thumb was stunted by the disease. Dr. Corlett remarked of this case that if he had seen it in Cuba he should have regarded it on first sight as a case of leprosy, so closely did the lesions simulate that disease.

SECTION ON GENERAL SURGERY.

Dr. W. N. WISHARD of Indianapolis, Chairman.

The first paper in this Section was read by Dr. H. W. LOEB of St. Louis, entitled,

SOME ILLUSTRATIVE CASES OF NASAL HEADACHE.

The author at the last meeting of the Missouri State Medical Association presented a paper upon nasal headaches in which the following list of such conditions was suggested as possessing an etiological significance in this regard: acute inflammations of the nasal mucous membrane, chronic rhinitis, rhinoliths and foreign bodies, septal deformities, deflections, spurs, ridges, diseases of the accessory sinuses, chronic atrophic rhinitis and anything which causes the middle turbinated tissues to press against the septum. In headaches of the following characters it was stated that a nasal origin might be expected: 1, frontal headaches; 2, hemicrania, starting about the orbit; 3, long continued headaches; 4, headaches of which successive attacks are identical or similar; 5, headaches increased or originated by acute rhinitis; 6, headaches associated with evident disease of the nose or accessory cavities. In the present paper the author presented cases which illustrated the characteristics, both symptomatic and causal, as stated in the before mentioned contribution.

Dr. M. MERRILL RICKETS of Cincinnati, reported several interesting surgical cases, and exhibited photographs of the same.

Dr. J. T. BERGHOFF of St. Joseph, Mo., read a paper entitled,

TREATMENT OF FRACTURES OF THE LEG.

In treating fractures of the leg, the author said the latter should never rest on the bedding but should be suspended. He cares not how well the surgeon may coaptate the broken bone and protect the same with bandages, or plaster-of-paris, if the limb rest on the bedding, by each movement of the body of the patient the fracture is bound to move. The process of repair is exactly the same in soft tissues and bones. Why do we have union by first intention? Because we coaptate the wounds exactly, and keep them so. The wound heals sometimes in three days, at the farthest a week. But to put the broken limb in an immovable condition and keep it so without great suffering to the patient can not be done under the old system. Dr. Berghoff then described an apparatus or splint, the outgrowth of patient study for twenty years, but more particularly the last ten years. The apparatus is also adapted for treating disease of the hip, knee and ankle joints, as the extension can be adjusted as the case requires, the joints being kept immobile.

INCURABILITY OF ADVANCED AND EXTREME CASES OF TALIPES EQUINUS VARUS BY THE MEANS AND METHODS IN VOGUE AT THE PRESENT TIME; SUGGESTION OF A WAY TO REMOVE THE DEFORMITY WITHOUT DISTURBING THE USEFULNESS OF THE EXTREMITY.

The author of this paper, Dr. LOUIS RAYER of St. Louis, presented a plaster cast of a talipes equino-varus in which the weight of the body rested upon the dislocated astragalus and calcaneum. He produced also the skeleton of a leg and foot of a person who died while in this condition. He showed that there was complete dislocation of the astragalus; that the knee joint surfaces had formed between that bone and the calcaneum, whereby the weight of the body rested entirely upon the end of the astragalus and calcaneum; that the scaphoid and other bones of the foot bore little if any part in sustaining the weight of the body. It was found impossible in extreme cases of talipes to rest the foot in its natural position by tenotomy or by

In one case, after six years' trial, the doctor had proposed an amputation similar to Chopart whereby all

bones anterior to the astragalus were removed. The operation would leave a linear scar anterior to the astragalus in its new position and would be out of the way, and in such direction the artificial foot could be easily adjusted. He had not had an opportunity of trying this method, but felt sure that this amputation was a proper method in those cases where, after long continued efforts, reduction could not be effected. He also reported a case where there was extreme lateral curvature of the spine from distortion of the pelvis in a young musician. He became satisfied that the deformity was due to the unnatural position, and therefore directed a long splint applied reaching from the axilla to the foot and the pelvis was gradually pressed toward the splint by an appropriate bandage. After a period of time, not stated by the speaker, the patient recovered.

In the discussion which followed, Dr. MARSEE of Indianapolis, took strong ground against tenotomy, tarsotomy, or amputation in these cases, holding the position that by *brisement* forced with a wrench or club-foot stretcher he could bring the most refractory case into normal position.

Dr. WM. E. WIRT of Cleveland, believes in resection of some of the bones after the method of Phelps in cases where tenotomy or linear osteotomy had proved unavailable.

Dr. JOHN B. HAMILTON of Chicago, agreed with Dr. Marsee in recommending the use of a club-foot stretcher or wrench. He would not hesitate to apply a force sufficient to comminute the dislocated astragalus if it were necessary to put the foot in position. He had seen no bad results following osteoclasis. The difference between osteoclasis, osteotomy or tarsotomy is precisely that between a simple and open fracture. In regard to abrasions of the skin, he had not met with any, and strongly preferred osteoclasis.

Dr. ALLAN DE VILLIERS of Toledo, Ohio, read a paper entitled,

NEW DEVICES FOR CUTTING BONE.

Dr. De Villiers exhibited a surgical motor with various forms of saws and drills, which he developed through a series of practical tests. He had used them first upon the dead, afterwards upon the living. These instruments were adapted for operation upon the skull, maxillary bone, ribs, nasal bones, etc.

Dr. WILLIAM E. WIRT of Cleveland, Ohio, read a paper on

THE TREATMENT OF OLD CASES OF HIP DISEASE.

He said there is no doubt that if convalescent cases of hip disease were carefully and persistently treated during a long period of complete recovery, whatever deformity had existed up to this time and that which accompanies this period, could be entirely overcome without operation. When shall a case of hip disease be considered to have progressed far enough to permit the removal of the extension splint and the substitution of a convalescent brace? The solution of this problem was a matter of judgment. It is better to allow the extension splint to be worn unnecessarily long than for the substitution to be made too soon.

The deformities requiring correction are flexion and adduction. Dr. Wirt had been surprised in several instances of old cases of hip disease with considerable deformity where, after the application of continuous extension in bed for a few weeks the deformity would be considerably reduced. After a trial of extension in bed with a failure to reduce deformity there remains as a means of correction: 1, brisement forced, with or without myotomy, tenotomy, fasciotomy, etc.; 2, osteoclasis; 3, osteotomy. These operations were then considered by the author under their respective heads. Osteoclasis and osteotomy are reserved for those cases in which there exists bony union or a fibrous ankylosis of a very firm character. The author reported sixteen cases following Grant's operation.

A CASE OF SENILE GANGRENE TREATED BY AMPUTATION.

This paper was contributed by Dr. G. W. H. KEMPER of Muncie, Ind. The patient was a farmer aged 73 years. After detailing the particulars of the case the author drew the following deductions:

1.—While the gangrene is confined to one or two toes, it is best to defer amputation. If the disease extends to the dorsum of the foot amputation is proper.

2.—Amputation below the knee is rarely successful, owing to lack of proper blood supply and tendency to recurrence of gangrene in the stump.

3.—Amputation through the thigh will save a large per cent. of the cases, and especially so when the subjects are free from a general disease. Mounssell-Moulin observes that usually the thigh is small and wasted in the lower

third; the artery is sound in Hunter's canal, the veins are well supplied with blood, and old people as a rule resent operation very slightly. Their tissues are not prone to inflammation.

4.—When amputation has been performed below the knee, and gangrene appears in the stump, unless the patient is exhausted, it will be proper to perform a secondary amputation above the knee.

Dr. J. N. QUIMBY of Jersey City, N. J., read a paper entitled,

A NEW METHOD OF OPERATING AT THE ANKLE JOINT FOR INJURIES OF THE FOOT.

The method consists of making a curvilinear incision across the dorsum of the foot, commencing anterior to and a little below the internal malleolus, and terminating at a corresponding point a little below the external malleolus, and then uniting the two extremities of the dorsal section by an incision across the sole of the foot, forming an anterior and posterior flap, similar to the operation performed by Progoroff of Russia. After forming a short anterior flap and turning it back, he then dissects out the astragalus from its attachments, being careful to keep close to the bone; then forming a linear posterior flap from the sole of the foot he makes a careful dissection, exposing the anterior half of the calcaneum. This being done, and the soft parts being well retracted by an assistant, the saw is applied so as to remove nearly the anterior half of the bone by an incision from above downward and from behind forward. The sharp edges of the remaining portion of the bone are then rounded off and the sawed surface is applied directly to the articular surface of the tibia between the malleoli, without removing any part of the cartilaginous surface. After stitching up the flap in the usual way a strap of adhesive plaster is applied three or four inches in width extending from the upper portion of the gastrocnemius muscle to a corresponding point on the anterior surface of the leg passing directly over the os calcis, so as to keep closely and firmly in apposition to the articular surface of the tibia, which is kept there until the union of bones has taken place.

THE BACTERIA OF THE SURFACE.

Dr. FRANK J. THORNBURY of Buffalo, read a paper under this title in which the latest researches were set forth, rational mechanical means of disinfection summarized, and the non-utility of antiseptics proclaimed. The varieties of organisms which the cutaneous and mucous surfaces present in great abundance comprise molds, yeast fungi, bacilli, cocci, color and odor-producing bacteria. The hairy regions, as the axillary space, and the interdigital folds are the places of predilection for the bacteria upon the cuticle. Myriads of microbes are present in the oral cavity, the intestinal tract, the genital tract of the female, the male urethra, and in the conjunctival secretion and crumen of the ear. Among the masses are germs which are pathogenic, as the *Fehleisen streptococcus* of erysipelas. The cleansing of the surface constitutes one of the most important duties of asepsis. This pertains especially to the physician's own hands. The disinfection can not be accomplished by the use of antiseptics, so-called, which do not even reach the bacteria imbedded in the substrata of fat and dirt. The disinfection must be mechanical, dislodging away the glandular secretions, dead epidermal cells, vegetable and albuminous substances. For the latter purpose soap, hot water and brush are used, aided by alcohol and ether, and rubbing with sterile towels. Baths are an important adjunct to asepsis, and one or a number should be administered previous to operation.

THE ETIOLOGY, DIAGNOSIS AND TREATMENT OF ULCERATION OF THE RECTUM.

This subject was dealt with in a general way by Dr. JOSEPH M. MATTHEWS of Louisville. As a matter of convenience he classified these ulcers under four heads: benign, malignant, tubercular and syphilitic. He said to this division there might be a valid objection based upon correct pathological grounds. For instance, in this classification he makes the term, malignant, synonymous with cancer, and yet the tubercular ulcer may in truth be malignant without assuming the characteristics of cancer. Again, some writers would have us believe that a tuberculous patient is closely akin at least to a syphilitic one or vice versa. Benign ulceration is not so frequently found in the rectum as is supposed. Whenever the author meets with a well-defined ulceration existing in the rectum, he immediately begins to suspect some special diathesis. It is only when the facility of defecation

is interfered with that any danger is to be feared. The common of this portion of the gut is not harmed by any ordinary causes. For these and other causes Dr. Matthews has long since been forced to believe that such ulcers are caused as pregnancy, dysentery, etc., were of great factors in producing ulceration of the rectum. The speaker then dwelt upon malignant ulceration of the rectum, saying that is a favorite seat for cancer. Many times the disease is overlooked entirely or diagnosed as some other affection. It has occurred to him, several times to have had patients referred to him for some trivial rectal trouble and found cancer instead. The more he practices the more he is convinced that syphilis is responsible for fully one-half of the cases of severe ulceration of the rectum. The treatment must in every individual case depend upon the known character of it. We can not treat a benign ulcer as we would a malignant one, nor a tubercular ulcer as a specific one, nor the last named as the first named. Benign growths of the rectum require local applications. Malignant, extirpation; tuberculous, the chetere, syphilitic, antisyphilitic and local medication, extirpation, colotomy.

INTERNAL COLOTOMY.

Dr. LEON STRAUSS of St. Louis, read a paper with this title in which he entered a plea for more frequent and earlier colotomy in painful malignant diseases of the rectum. Dr. Strauss stated his reasons for making colotomy as follows: 1. It is the greatest modern surgical relief means, inasmuch as it completely does away with the function of the rectum, thereby relieving the intense pain caused by defecation. Pain is an inevitable result in advanced malignant disease of the rectum. There are few exceptional cases which only prove the rule; 2. the lease of life is extended. There are many instances where it has been considerably extended. So great authorities as Cripps, Allingham, and Esselsberg claim to have extended the ease for weeks or months. Are not these most cogent reasons for making a colotomy? 3. the risk of the operation has been minimized. Allingham has made sixty-eight colotomies with only two deaths, and they were total obstruction cases. Cripps forty-eight with one death; this was a total obstruction case. Edwards has made sixteen, with one death. The patient was very septic at the time of operation. Reeves has made sixty-five operations without a death. Goodall has made twenty-two without a death. Statistics show a death rate of less than 2 per cent. By making early colotomy the author believes that the death rate might be reduced to less than 1 per cent.

Dr. WM. THOS. CORLETT of Cleveland, Ohio, read a paper on

THE CLINICAL VARIETIES AND TREATMENT OF PEMPHIGUS.

His paper was illustrated by the description of unusual cases. The writer divided pemphigus into two main varieties, *acute* and *chronic*, and *subacute*, under which all cases, although differing in certain features, may be grouped. Under acute pemphigus he gave the history of an epidemic of pemphigus in the newborn. The main features were that all the cases occurred in the tract of one midwife, the disease began at the end of the first week, as an erythema on the lower part of the face, or upper part of the chest. This was followed by the formation of blisters with flabby walls which soon ruptured leaving extensive raw surfaces. About three-fourths of the body was involved and terminated fatally about the tenth day. The writer regarded it as due to contagion.

Under chronic pemphigus, which is the most common form, Dr. Corlett drew attention to the frequency with which the mucous membranes were involved and cited a case in which the disease first appeared in the oropharyngeal tubes simulating capillary bronchitis. Later it appeared in the mouth and throat, which from its resemblance to diphtheria had been called pemphigus diphtheriticus. Finally the disease attacked the eyelids. On the skin it differed in no way from the usual form. The case ended in recovery, but with the complete loss of sight.

In the treatment, he thought arsenic had been overestimated. Iron, strychnin and arsenic benefited only as general tonics, while were especially indicated in this disease. Locally, the continuous tepid bath was recommended, but unfortunately it is often impracticable, when recourse must be had in simpler measures. As soothing applications, the glycerol of tartar, one part to three or four of distilled hamamelis, or water, or the glycerol of lead, one ounce to a pint of water, he thought the best at our command. The latter was preferred when but small areas were denuded of epidermis. When itching is present, a 3 per cent. solution

of resorcin was recommended. Finally when desquamation sets in, some emollient, such as the zinc ointment or carbolized vaselin will afford the best relief.

KRASKE'S OPERATION WITH REPORT OF CASES.

By DR. H. O. WALKER of Detroit, Mich. The author of this paper said that a man or woman who had cancer of the rectum was of few days, and the method of relief could be done in three ways—either by proctotomy and scooping away of the growth, by excision of the cancer, or by colotomy, all of which were temporary, as the author had never seen a case of true cancer that ever got well. When the malignant growth was high up, say two or three inches above the rectum, the best operation to make would be by Kraske's method; that is, by making an incision down through the second sacral vertebra to the anus to the left of the coccyx, and rapidly stripping off the muscular and ligamentous attachments to the coccyx and cutting them away with the bone forceps and as much of the sacrum as is necessary to expose the growth. Then we have a full view for enucleating the growth and excising it. It is well known that it is a difficult matter to approximate the ends by suture method, and an idea was forced upon Dr. Walker from his knowledge of the Murphy button that with a large button, say two inches in diameter, which he exhibited to the Association, he could approximate the cut ends of the rectum, and by this means prevent the infiltration of fecal matter to approximate the ends by suture method, and an idea was forced upon Dr. Walker from his knowledge of the Murphy button that with a large button, say two inches in diameter, which he exhibited to the Association, he could approximate the cut ends of the rectum, and by this means prevent the infiltration of fecal matter, which by the other method was an impossibility. In this connection, Dr. Walker said he had made the first end-to-end approximation by the Murphy button in a case of fecal fistula on the 8th of December, and the patient on whom he had operated made a good recovery and within two weeks was as well as ever, with no evidence of any contraction of the intestine.

SOME HERESIES REGARDING PROSTATIC PATHOLOGY.

This paper was contributed by DR. G. FRANK LYSTON of Chicago. The author said among the many ills which were marked *noli me tangere* until recent years, and which modern surgery has done much to relieve, prostatic hypertrophy occupies a very prominent position. The surgical resources at present at our command were then briefly stated. The author is becoming daily more and more firmly convinced that the ideal operation is a combined suprapubic and perineal section performed at an early period. He believes that in many cases this early operation will not only forestall circumscribed prostatic obstructions, median or lateral, but will prove directly curative by restoring the normal function of micturition. Supra-pubic cystotomy is undoubtedly the best method of draining the bladder, as far as a single operation is concerned, and in many instances it is all sufficient. When combined, however, with perineal section, prostatic dilatation and prolonged drainage by a large tube, we often do away with certain conditions which exist in the way of contracted lumen of the prostatic urethra and hyper-excitability of this portion of the urinary tract, which supra-pubic cystotomy alone might not accomplish.

Dr. Lyston believes that the main factors in the etiology of prostatic disease are laid down in many cases, if not the majority, before middle life.

The surgical address before the general session was given by DR. HENRY O. MARCY of Boston, the subject having been selected by a request, as that of

INGUINAL HERNIA, ITS ANATOMY AND BETTER METHODS FOR CURE.

Dr. Marcy illustrated his lecture by a series of slides reproducing the magnificent illustrated work of the old masters—Kamper, Cooper, Scarpi, Bougoyre, and others. By general consensus of opinion the profession is indebted to Dr. Marcy as an innovator in this field of labor. He had established the value of the buried animal suture and published his results quite five years before that of Weith of Germany, to whom in Europe the credit is generally attributed. The essential principles of his operation for hernia have become universally accepted. The result of the work of a large number of the modern operators give from 70 to 90 per cent of permanent cures. In resuming Dr. Marcy stressed the peritoneal sac as a rule should be resected and resting quite to its very base; that the deeper structures of the sac make up the posterior wall of the inguinal

canal should be reinforced and restored to their original normal condition; that the external wound should be closed without drainage and the skin wound sealed with iodoform collodion. In his large experience involving several hundred cases, he states that where the intestine has not been involved from strangulation or other cause, not one of his patients has appeared to approach the danger line, and that of the entire number which he has been able to trace, more than 90 per cent. have remained after one year permanently cured.

Papers were also read before this section by Drs. WILLIAM N. WISHARD of Indianapolis; J. McLEAN MOULDER of Kokomo, Ind.; WILLIAM T. BELFIELD of Chicago, and others.

Committee on Nominations organized by election of Dudley S. Reynolds of Louisville, chairman and I. N. Love, secretary.

The following officers were elected for the ensuing year: President—Dr. X. C. Scott of Cleveland, Ohio.

First Vice-President—Dr. Leon Straus of St. Louis.

Second Vice-President—Dr. G. Frank Lyston of Chicago.

Secretary—Dr. Frederick C. Woodburn of Indianapolis.

Treasurer—Dr. George J. Cook of Indianapolis.

Chairman, Com. of Arrangements—Dr. Thos. E. Holland of Hot Springs.

Hot Springs, Ark., was selected as the next place of meeting. Time of meeting, first Tuesday in November.

After drafting and adopting resolutions of thanks, the Association adjourned.

Tri-State Medical Association.—The Tri-State Medical Association of Arkansas, Tennessee and Mississippi will convene in annual session in Memphis, Tenn., on Nov. 22 and 23, 1893.

Members of the Association and all regular physicians in good standing are cordially invited to attend.

Those intending to contribute papers or report cases of importance occurring in their practice, should notify the Secretary at once, giving title of paper, in order that their names may appear on the program. A. L. ELKAN, M.D., Secretary, Memphis, Tenn.

West Tennessee Medical and Surgical Association will meet at Brownsville, Tenn., Thursday, October 26, at 2:30 p.m. A session will be held also at night and one on Friday morning, the 27th. This arrangement is made to save time, and to avoid night travel. Dr. I. A. McSwain is the Secretary.

Mississippi Valley Association Notes.—The *Indiana Medical Journal* will in its next issue print the proceedings in full. Among the medical editors present, we noticed Dr. R. E. Granger of the *New York Medical Journal*; Dr. Brayton of the *Indiana Medical Journal*; Dr. Culbertson of the *Lancet and Clinic*; Dr. I. N. Love of the *Medical Mirror* of St. Louis; Dr. G. F. Lyston of the *Western Medical Reporter* and Dr. John B. Hamilton of this *JOURNAL*. Dr. James F. Hibberd the President-elect of the American Medical Association gave the annual address in medicine. The reception was held at the Denison House, and Governor Matthews honored the occasion by his presence. The Chairman of the Committee of Arrangements, Dr. Cook, and the secretary of the Association, Dr. Woodburn, have reason to be gratified at the success of the meeting.

Tri-State Medical Association of Alabama, Georgia and Tennessee to be held at Chattanooga, Tenn., Oct. 17.

ASSOCIATION NEWS.

The Journal of the American Medical Association.—"Since the meeting of the Medical Association at Milwaukee, we have watched this journal with unusual interest, because its new editor was not only so well known to the profession at large, but also because he came from our own city; and, therefore, any success he might achieve would reflect so we argued, credit upon the city from which he came. That Dr. Hamilton has fulfilled the highest expectations of his friends goes without saying. The profession should take great pride in making this journal its representative both at home and abroad. We are equal in every way to our friends across the water, and there is no reason why, in the matter of a representative journal, we should not certainly equal, if not excel them. That the JOURNAL will do this under the editorial management of Dr. Hamilton we firmly believe. But he must be supported, of course, by the whole profession. This can not be done in any better way, than by sending the annual subscription of \$5.00 to the JOURNAL, at 68 Wabash Avenue, Chicago."—*E. J.*, October, 1893.

NECROLOGY.

Dr. Edward Warren-Bey, whose death has recently been announced, has for nearly twenty years been one of the leading physicians of Paris, and of worldwide reputation. He was born in Tyrrell County, North Carolina, Jan. 22, 1828. His parents were natives of Virginia. His father, Dr. Wm. C. Warren, was a man of intelligence and good professional attainments. When the subject of this sketch was but 4

years of age his father removed with his family to Edenton, N. C. When of a proper age the boy was sent to the Fairfax Institute, near Alexandria, where he remained for two years, and was then placed at the University of Virginia, where he won honors and received diplomas, and by selection, delivered the valedictory before the Jefferson Society. In 1851 he graduated from the Jefferson Medical College, Philadelphia.

It is stated by one of his biographers that while pursuing his studies in Philadelphia he conceived the idea of administering morphia under the skin for the relief of pain by puncture with Anel's syringe. He had written a thesis for graduation on this method of administering medicines, but mentioning it to one of the faculty, who looked upon it as chimerical and dangerous, he was dissuaded from presenting the paper and wrote one on another subject. He had, however, become so thoroughly convinced of the practicability of the method that he soon after put it to a practical test, and was some four years in advance of the public announcements of this very useful method of administering remedies.

To farther prosecute his medical studies he spent most of the years 1854 and 1855 in attending the hospitals and clinics of Paris, and during this time formed strong and lasting friendships with many of the leading medical men of France. He was a ready and a graceful writer, and contributed from the French capital a number of very acceptable articles to the *American Medical Science*, and to other American medical publications.

On returning to the United States he settled to practice in Edenton, N. C. He was thoroughly well equipped to practice medicine and speedily acquired a leading position among the medical men of the region. In 1856 he was selected to deliver the annual address before the State Medical Society, which was well received and brought him prominently before the active workers in the professional ranks. The same year he obtained the "Fish Fund Prize" for an essay on the "Effects of Pregnancy on the development of Tuberculosis." This paper has passed into the permanent literature of medicine. In 1857 he was elected editor of the *North Carolina Medical Journal*, at the time the official organ of the State Medical Society. The Gynecological Society of Boston the same year elected him a member. While in Paris he became a member of the "American Medical Society of Paris," and this organization sent him as their delegate to the American Medical Association, but he was unable to attend or register. But he was a delegate from the State Medical Society of North Carolina to the meeting of the American Medical Association, at Louisville, Ky., in 1856. He also attended meetings in Baltimore, Md., where he was then practicing in 1857, 1858, 1859, 1870, and 1871.

Dr. Warren was on Nov. 16, 1857, united in marriage to Miss Elizabeth Cotton Johnson of Edenton, a most estimable lady whose ancestors were extensively connected with many distinguished families in the old North State and in Virginia.

Dr. Warren's reputation for learning and scientific attainments had become so widely known in 1859 that he was elected professor of materia medica and therapeutics in the old and prosperous University of Maryland. This led to his removal to the city of Baltimore. The same year he was elected the first vice-president of the Association for the revision of the United States Pharmacopœia. In the University of Maryland he at once took high rank as an able teacher and an attractive lecturer.

On the breaking out of the war between the States he threw his fortunes with his native State and his friends in the South. He served in the field, in hospitals and on medical boards. He was chief surgeon in the North Carolina

Navy and medical director of the Cape Fear section. He was also for a time the chief medical inspector of the Department of Northern Virginia. He was twice promoted for his efficiency and courage on the field of battle. This trait of efficiency in the doctor was so notable as to attract attention, and the fact coming to the attention of the Assembly of North Carolina, an Act was passed by them raising his rank from that of colonel to that of brigadier-general for "efficient services rendered to sick and wounded."

Notwithstanding the engrossing official and professional duties of Dr. Warren during the war, he wrote a work to meet the needs of surgeons in the field, entitled, "Surgery for Field and Hospital." In this publication, which was well received and speedily passed through two editions, the doctor made some valuable original suggestions. In 1865, Dr. Warren resumed his residence in Baltimore, expecting at the same time to resume his professional duties in the University of Maryland. But the changed conditions of the country and the status of the Southern States, the policy of the general government and local interests combined to close the doors of that institution against him.

He was not only capable but ambitious and full of energy, and it was mainly at his suggestion and through his efforts that the old Washington University Medical School was revived and rapidly rose to have a commanding position and an able faculty and good patronage. In this faculty Dr. Warren filled most acceptably the chair of surgery.

When the Act of Assembly of Maryland passed requiring an examination and registration of the physicians of the State, Dr. Warren was appointed upon the board to carry the law into effect.

In 1868 he was elected one of the vice-presidents of the Medical and Chirurgical Faculty of Maryland, and the same year founded the *Medical Bulletin*, which under his management acquired a large circulation.

The celebrated Wharton trial, which took place in 1872, brought Dr. Warren to the forefront among specialists in criminal trials. He was confronted by able physiologists, general practitioners and chemists, and their theories and tests shown to be inconclusive. The case attracted wide attention not only in America but in Europe. Dr. Warren ably sustained himself before the court, and his testimony so completely broke down the chemical evidence relied upon by the prosecution as to compel the court to enter a *nolle prosequi* in the case. For some time after the doctor was made a target for critics, not only in the medical profession but by the bar and the public press. But it is simple justice to say that no review of his evidence and theory of the case was ever able to demonstrate that he was in error in his views.

At the meeting of the American Medical Association in 1872 he was chosen Chairman of the Section of Surgery for the following year. He did not, however, attend that meeting or send a report.

In 1873 Dr. Warren suffered a severe domestic affliction in the death of his devoted wife. His health suffered seriously and to change the scene he consented to accept a medical position in the Army of the Khedive of Egypt. His service although brief in that country was nevertheless sufficiently conspicuous to place him at the head of the surgical staff. It was his good fortune to relieve Kissim Pasha the Minister of War from a strangulated hernia.

This operation was undertaken when the war minister's life was despaired of by his own surgeons, and when it was almost impossible for Dr. Warren to get any of them to assist him in the operation from a religious dread of being blamed with causing his death. But the operation was a success and the result placed the courageous Dr. Warren in the front rank of surgeons in the Khedive's army.

His splendid success where death was imminent and expected, induced the Khedive to confer upon Dr. Warren the Decoration of the Medjidie and the title of Bey.

Dr. Warren unfortunately contracted a severe form of ophthalmia common in the East and it proving obstinate, he obtained a furlough for six months to visit Paris for treatment. Here he was promptly told that one eye was practically lost and that a longer residence in Egypt would result in the loss of the other.

He had no alternative but to resign, which he did. The Khedive was most kind, and in accepting his resignation spoke of his valuable services in the Egyptian army and wished him long years of usefulness.

It was then while still under treatment that he was advised to become a candidate for practice in Paris. After many conferences with friends and the earnest advice of Dr. Charcot, Bredd and other eminent practitioners, he concluded to take up his permanent residence in Paris.

Dr. Warren's success in the metropolis of France was exceptionally rapid and gratifying. Both practice and honors came flowing in upon him. From Spain he received the decoration of a "Knight of the order of Isabella the Catholic," for earnest services rendered to Spanish subjects, and from his old Maryland a degree of "Master of Surgery."

Dr. Warren both as a boy and through his life proved his indomitable energy and power of work. He secured a large share of confidence with his professional brethren. And yet like all men of force and original ideas, antagonisms were evolved by the friction. That he was a man of ability and culture his life and works attest. His house in Paris was frequented by Americans and travelers from other countries, and his attentions and hospitalities for years generously bestowed upon numerous friends visiting Paris.

J. M. T.

Dr. Thomas Lincoln Richards of the Vanderbilt Clinic of New York city, died Sunday, October 1, at the age of twenty-nine years. His malady, so seldom fatal among physicians, was smallpox, contracted while in the performance of his duty at the clinic. A patient was under treatment for varicella by one of the staff, who exhibited the case freely as a typical case of that disease. Two physicians were taken ill about the same date; one of them recovered and one, Dr. Richards, succumbed to what at first appeared to be a mild form of variculous disease. He was an alumnus of the College of Physicians and Surgeons, New York, and an ex-interne of the Bellevue Hospital, during 1892. His former home was at Fort Atkinson, Wis. It is an extremely infrequent event, so far as can be ascertained from the periodical literature of medicine, that a physician falls a victim to variola. In this case of Dr. Richards, the attack did not at first seem serious, neither did he seem to suffer in consequence of his removal from his home in the city to the Contagious Disease Hospital on North Brother Island, but he grew worse from day to day after his removal. Dr. Richards was unmarried.

Dr. T. J. Sprague of Joliet, Ill., lately appointed pension examiner, died October 3.

BOOK NOTICES.

System of Diseases of the Ear, Nose, and Throat. Edited by CHARLES H. BURNETT, A.M., M.D. Emeritus Professor of Otolaryngology in the Philadelphia Polyclinic, etc. Philadelphia, Pa. Vol. II. Illustrated. Philadelphia: J. B. Lippincott Company. 1893.

This is an important work of 858 pages, containing six papers on diseases of the nose, and seventeen on throat affections. Of the twenty-three writers New York is represented

by seven, Pennsylvania four, Michigan two, and several other States by one each. One foreign country, England, is also represented.

The book is well illustrated with many plates and figures. Some of these are exceptionally finely executed, the plates being introduced in separate sheets.

W. C. Jarvis has a 28-page article on surgical procedures in deformities and neoplastic growths in the nose. It is prepared with great care and thoroughness, and the fairness and generosity of the author are conspicuous on every page in the numerous references to other authors, and the credits duly accorded each for originality and priority in discoveries and methods.

J. A. White gives the most elaborate elucidation of the subject of neuroses of the nose we have ever seen. He devotes fifty-eight pages to this topic. His exposition of the nasal reflexes is clearly abreast of the times and is full of proof of extensive research. The importance of recognizing and properly treating nasal reflex cough is shown in the misery and expense endured by those sufferers who are annually dragged from their homes and family ties to spend their winters in the south or the mountains of the West, only to find at last that a little judicious treatment of a nasal affection banishes the specter of phthisis.

Dr. White has obtained the best results in treating paroxysms of asthma, by spraying the nose with a 4 per cent. solution of cocaine followed by a second spray of camphor-menthol, 6 per cent. Cerebral sedatives and vaso-tonics are added.

A. W. MacCoy has a beautifully illustrated paper of twenty pages on the anatomy and physiology of the pharynx and larynx.

Max Thorner has written twenty-four pages of great practical value on the various forms of acute pharyngitis. He opens with an interesting discussion of the mooted question of taking cold. He pays doubtful respects to the old theory, and discreetly steps out of the arena while he introduces the several disputants to fight it out among themselves. His remarks on treatment embrace the most valuable of the new remedies.

E. F. Ingals has twenty pages on chronic pharyngitis, in which no space is wasted in historic disquisition or references to other writers. He records merely the results of his own observations and rich experience, in smooth, flowing English.

W. C. Glasgow, in treating of croup, throws discredit on the time-honored remedy, calomel, for preventing the fibrinous exudate. Otherwise his treatment is orthodox. He indorses Dr. Wetmore's iron treatment.

J. L. Smith, in an exhaustive paper of forty-seven pages on diphtheria, maintains that it is primarily a local disease of microbic origin. His warnings against that undeservedly popular remedy, potassium chlorate, are telling and timely. He uses H_2O_2 in 10 per cent. solution for spraying the throat. A good dioxide of hydrogen is neither toxic or irritating, and gives the best results in full strength. No opinion is expressed in the efficacy of sulpho-calcin or methyl-violet. Corrosive sublimate is recommended internally and locally, but pilocarpin is condemned.

J. Solis Cohen brings the volume to a close with an admirable treatment of a most difficult subject—tuberculosis and syphilis of the larynx. In tuberculosis he places reliance on creosote internally, and lactic acid topically, and is opposed to the galvanocautery. Twenty per cent. solutions of menthol in olive oil are injected into the larynx.

A Treatise on Ophthalmology for the General Practitioner. Second edition, revised and enlarged, with 140 illustrations, by Adolph Alt, M.D. Svo. cl. pp. 330. St. Louis: J. H. Chambers & Co. 1893.

That the book was acceptable to those for whom it was intended is evident from the fact that it has now passed to its second edition. It is divided into twenty-eight chapters. The first gives the anatomy of the eye and its appendages; the second the method of examination. Chapter six being on "Minor Manipulations in the Treatment of Eye Diseases," is dislocated by being placed between chapter five on diseases of the orbit, and chapter seven on diseases of the orbit. The remarks on asepsis and antiseptics are excellent so far as care of the instruments are concerned, but a little more detailed direction of the precautions on the part of the practitioner, would have added to the value of the book. While there are operations illustrated and described that the general practitioner will rarely, if ever, perform, there is so much of value that we unhesitatingly commend the work to those for whose instruction it is intended.

State Medical Association of Texas.—Transactions for 1893. This volume includes the report of the transactions of the twenty-fifth annual meeting, which was held at Galveston in May, 1893. There are several notable papers in the transactions, and no pains have been spared apparently to render the book typographically the equal of other State transactions. A glance at the papers shows them to be complete, and at the same time not so "long drawn out" as to be tedious. The book has been carefully edited by the competent secretary, Dr. H. A. West of Galveston, Texas.

The American Association of Physicians and Surgeons.—Transactions for 1893. The ambitious title of this Association would lead us to expect that its transactions would show superior work, and a glance at the volume proves that the expectations are well founded. It includes papers by Drs. Beverly Robinson, Andrew H. Smith, Gilman Thompson, Tyson, Whittaker, Wood, Theobald Smith, Osler, Councilman, Allen Starr and others. The articles are illustrated by carefully drawn diagrams and well colored lithographs. As the papers have been generally printed elsewhere, either in abstract form or otherwise, special reference to them need not be made here.
